DATA FROM THESE TABLES MAY BE REPRODUCED WITH ACKNOWLEDGEMENT OF SOURCE

## FORWARD

This Population Projections and Estimates report was published by the Central Statistics Office in collaboration with Dr. Valerie Nam, consultant (UNECLAC). The purpose of this publication is to provide Demographers, Planners, Research Workers and the General Public with time series of the population by age, sex and district.

The Central Statistics Office wishes to first and foremost acknowledge the technical assistance received from the United Nations Economic Commission for Latin America and the Caribbean (UNECLAC) as well as the assistance received from the Ministry of Health (Epidemiology Unit) and the Registry of the Civil Status.

Notification of errors and omissions as well as suggestions for improvement are welcome.

## DIRECTOR OF STATISTICS

January 2019

## ACKNOWLEDGEMENTS

The department would like to acknowledge the technical assistance and cooperation it has received from the United Nations Economic Commission for Latin America and the Caribbean (UNECLAC). The department also wishes to express sincere gratitude to the Ministry of Health and Wellness (Epidemiology Unit) as well as the Registry of Civil Status for making available the required records for the extraction of baseline the data needed to facilitate the production of population estimates and projections.

The Department wishes to recognize the efforts of the staff members of the Demographic Unit who participated in the preparation of this report, Ms. Diana Emmanuel and Ms. Nicole Regis.

The compilation of this report was executed by Dr. Valarie Nam and Ms. Linn Brown.

## Table of contents

## EXECUTIVE SUMMARY

This report presents mid-year estimates of the population of Saint Lucia for the period 2001-2014 and projections based on 2010 covering 2015-2030. The estimates are produced at the national and district levels by age and sex. The projections are at the national level only by age and sex.

Population estimates are generally classified on the basis of their time reference and how they are derived. The most common types of estimates are described as intercensal, postcensal and projections. Intercensal estimates relate to dates between two censuses and take the results of these censuses into account. Postcensal estimates relate to a past or current date following a census and take the most recent and possibly earlier censuses into account but not later censuses. Projections relate to dates following the last census, usually future dates, for which no current reports are available. The two most recent censuses conducted for Saint Lucia, the fourteenth and the fifteenth were conducted in May 2001 and May 2010. The series of intercensal mid-year population estimates presented cover the period 2001 to 2009. The postcensal estimates are from 2010 to 2014, 2014 being the most recent year for which vital statistics were available at the time of preparation of this report.

Assumptions of future growth are guided by past trends in changes of population and its components. Like many English speaking Caribbean countries Saint Lucia has a long history of census taking and vital registration dating back to the mid to late nineteenth century. Also, in common with many Caribbean countries, issues of quality and lack of access to relevant and required data from administrative sources and reduced public willingness to provide data for statistical purposes, have presented obstacles to the production of timely and reliable data.

Caribbean demographic development over the past thirty to forty years has followed a similar path to many developing countries. Fertility has declined quite markedly in the majority of developing countries and continues to decline everywhere as the fertility transition, the movement from high to low fertility is now almost universal. The average total fertility rate (the average number of children per woman) which was about 4.0 for developing countries in 1980-1990 was 2.8 by 2000-2010. For the Caribbean as a whole, the movement over the same period was from 3.3 to 2.4. It is within this context that demographic developments in Saint Lucia over the past thirty to forty years and the assumptions for future growth must be examined.

Since 1980, the population of Saint Lucia has been growing at a much-reduced rate. Between 1980 and 2001, the population grew at an average $1.5 \%$ annually. Since 2001, the rate has been cut drastically to $0.6 \%$. This reduction is primarily due to falling fertility levels. The average total fertility rate which was estimated at 4.4 in 1980 had dropped to 1.8 by 2010, a cut of $59 \%$.

The population at mid-year 2014 is estimated at 167,769 representing an absolute increase of just less than 11,000 since mid-year 2001. In percentage terms the increase was $7 \%$, which is representative of an average annual rate of growth over the 13 years of $0.52 \%$. An examination of growth for the two distinct periods representing the intercensal and the postcensal period shows an average annual rate of growth overall of $0.6 \%$ in the intercensal years due largely to the number of births recorded, 25,614 , with the resulting birth rate of 17.7 per 1,000 . For the years following, the growth rate was cut by one-half as the average crude birth rate fell to about 13 per 1,000 . While migration was reduced with the rate dropping from -5 per 1,000 to -2.3 per 1,000 , death rates remained stable at about 7 per 1,000 .

Of the total estimated 2014 population of 167,769 , females numbered 84,463 and males 83,306 . This represents an almost equal distribution of men and women in the population. Between 2001 and 2014, the male population grew much faster ( $8.5 \%$ ) than the female population (5.5\%). This showed a considerable drop in the excess of women over men from 3,338 in 2001 to 1,157 in 2014. The outcome was an increase in the sex ratio (the number of males per 100 females) from 95.8 per 100 in 2001 to 98.6 in 2014.

At mid-year 2014, the number of people under age 15 years numbered approximately 42,000 or $25 \%$ of the total population. This represents a decline in numbers of nearly 6,000 persons when compared with the 2001 population. At 2014, the youth population ages 15-29 years totalling about 43,000 persons accounted for onequarter of the population and showed a very small increase of 259 over 2001 . The prime working age population of ages 30-64 years increased by $27.6 \%$ from 53,797 in 2001 to 68,650 by 2014 and accounted for about $41 \%$ of the total population, up from $34.3 \%$. The large growth in this age group is primarily attributable to the ageing of the survivors of the high fertility periods of the past thirty to forty years. Occurring simultaneously with the decreases among the youngest age groups are increases among the oldest, the 65 years and over. An estimated 1,800 persons were added to this age group over the period, taking the proportion of the total population from $8 \%$ to approximately $9 \%$.

The method used for the population projections for Saint Lucia presented in this report is the Cohort Component Method. The component technique is based on assumptions about the components of population change: births, deaths and international migration. The projections produced in this report begin with a base population by age and sex at July 1, 2010 and using the cohort-component method which is based on age-specific estimates for fertility, mortality and international migration, the population is moved through 5-year time intervals to July 1 of the year 2030.

The data required for developing population projections using the Cohort Component Method are taken from population censuses, demographic surveys and vital statistics. The projections are produced using the United Nations Mortpak software package for demographic measurement. The required data inputs for the Mortpak software are produced using workbooks from the Population Analysis Spreadsheet (PASEX) series developed by the United States Bureau of the Census:

The following is a summary of the projection results:

- The pattern of population movements for Saint Lucia over the projection period is expected to vary based on the scenario assumed (see table (xx)). The population will increase continuously for both the medium and high variants based on assumptions of moderate and high fertility occurring simultaneously with moderate to high increases in life expectancy and small to moderate levels of migration. Under the medium scenario the total population at 2030 is estimated to be 172,241, reflecting an increase of 6,550 over the 2010 base of 165,691 . The movement under the high scenario is for an increase that is about 3 times the increase for the medium. By 2030, the population is estimated to be 185,657 , which is almost 20,000 higher than at 2010 . Under the low fertility scenario with small increases in life expectancy and a large volume of migration, there is a small increase of just fewer than 500 over the period 2010 to 2015. This is followed by a continuous decline which increases for each subsequent projection period. For the low projection the population is expected to dip to 159,860 , a fall of approximately 5,800 over 2010.
- In cases of population increases, average annual growth rates will remain low. The highest rate of increase observed for any five-year period is $0.68 \%$ for $2020-2025$ for the high projections. Under the medium scenario, growth rates are expected to remain at $0.2 \%$ over the entire period. Under the low growth scenario, the population is projected to show annual rates of decline from about $0.2 \%$ beginning in 2015 and thereafter at approximately $0.3 \%$.
- The annual number of births is expected to decrease consistently over the projection period for the low and medium scenarios only. According to the low projections, annual births fall by approximately $23 \%$, from 2,142 for $2010-2015$, to 1,660 by 2030 . The drop for the medium projections is by a smaller $10 \%$ from 2,280 at the initial period to 2,047 at the end of the period. For the high projections births will increase but slowly over the period. Under this scenario the average annual number of births is expected to move from 2,417 in 2010 increasing to 2,522 for 2020-2025 after which the number will drop to the 2030 estimate of 2,438 .
- Crude birth rates will decrease in all projection scenarios. The largest drop is observed for the low fertility scenario with the low projection showing a crude birth rate of 10.4 per 1,000 at 2030 down from 12.9 per 1000 at the beginning of the projection period. With moderate or high fertility assumptions, as in the case of the medium and high projections, the crude birth rate moves down from approximately 14 per 1,000 initially and by 2030 is about $12-13$ per 1000 .
- While the crude birth rate is projected to fall there is expected to be a small but steady increase in the numbers of deaths. Average annual deaths will remain between 1,100 and 1,300 . For the medium variant which assumes moderate increases in life expectancy, the average number of deaths per year will be 1,169 at the initial period rising to 1,248 at the end. Comparative numbers for the low and high projections are 1,179 and 1,157 respectively in the $2010-15$ period and 1,310 and 1,198 by 20252030. Death rates associated with these changes remain at an average of 7.0 per 1,000 over the period for the medium and high projections. The highest death rate observed over the period is 8.2 per 1,000 projected for the final five years of the low projection.
- According to the three projection scenarios, the population of Saint Lucia will continue to age over the coming decades. One indicator of ageing is the continuous decline in the number of children resulting from decreased levels of fertility. At 2010, the population 0-14 years old numbered approximately 42,000 representing approximately one-quarter of the total population. Under all three growth scenarios the population of this age group declines considerably. The reductions are to about 25,200 for the low growth, 30,900 for the medium and 36,500 for the high growth. In proportional terms the fall is projected to be from $25 \%$ at 2010 to approximately $16 \%, 18 \%$ and $20 \%$ for the low, medium and high projections respectively.
- The oldest population, persons of ages 65 years and over is projected to move in the opposite direction. In 2010 at the beginning of the projection period, the population in this age group numbered about 14,000 and accounted for about $9 \%$ of the total population. At 2030 this population group will account for an estimated $14 \%$ of the total population under all three growth scenarios. Under all three projection scenarios, the population of 65 years and over is projected to grow at rates far in excess of rates seen for the total population. Growth rates for the 65 years and over population are expected to be in excess of $2 \%$ per annum with the rate for the high projection being about $3 \%$ per annum.

## INTRODUCTION

Population estimates are generally classified on the basis of their time reference and how they are derived. The most common types of estimates are described as intercensal, postcensal and projections. Intercensal estimates relate to dates between two censuses and take the results of these censuses into account. Postcensal estimates relate to a past or current date following a census and take the most recent and possibly earlier censuses into account but not later censuses. Projections relate to dates following the last census, usually future dates, for which no current reports are available. An important aspect of the type of population estimates to be made relates to the definition of population employed for the estimate. Like census counts, estimates may vary as to whether they refer to the de jure (usual resident) population or de facto (physically present) population. In terms of geographical coverage, estimates may be for the entire country only or may include administrative regions. In the same way they may be for the total population only or for sex and age groups.

The two most recent censuses conducted for Saint Lucia, the fourteenth and the fifteenth, were conducted in May 2001 and May 2010. The series of intercensal mid-year population estimates presented in this report cover the period 2001 to 2009 . The postcensal estimates are from 2010 to 2014,2014 being the most recent year for which vital statistics were available at the time of preparation of this report. The estimates are produced at the national and district levels by age and sex. The projections are national and are based on the year 2010 and cover the period up to 2030.

Population Projections may be defined as "the numerical outcome of a particular set of assumptions regarding the future population. It is a conditional calculation showing what the future population would be if a particular set of assumptions were to hold true" (Siegel and Swanson 2004, 561). Smith et al (2001) elaborate: "Strictly speaking, population projections are conditional statements about the future. They show what the population would be if particular assumptions were to hold true. However, they do not predict whether those assumptions will actually hold true." Population projections are therefore not meant to be interpreted as forecasts or predictions but are simply illustrations of the growth and change in the population which would occur if certain assumptions about levels of fertility, mortality and international migration prevailed over the period covered by the projections.

Why are projections done? According to Siegel and Swanson $(2004,561)$ "perhaps the most important use of population projections is in the role they can play as a rational basis for decision making. Changes in population size and composition have many social, economic, environmental, and political implications. Population projections help decision makers in both the public and private sectors make informed choices." The Population Reference Bureau (PRB) summarizes this very important use. "Population projections provide policy makers and planners with a basis for assessment of future demand for resources such as food, water, energy, as well as services such as health and education. Projections alert policymakers and planners to major trends that may affect social and economic development and help them craft appropriate policies and programmes" (PRB 2014, 1).

## SECTION 1

## POPULATION ESTIMATES 2001-2014

## Size, Growth and Components of Change

The count of usual residents of Saint Lucia at the 2010 census was 165,591 , approximately 8,900 more than the count of 156,733 at census 2001. As will be described in the methodology presented as an Appendix to this section of the report, estimation of the intercensal counts at the middle of each year is based on a linear distribution of the components of the difference between the two censuses. Table (i) presents the series from 2001 to 2014. The table shows an estimate at mid-year 2014 of 167,769 which was an absolute increase of just less than 11,000 since midyear 2001. In percentage terms the increase was $7 \%$, which is representative of an average annual rate of growth over the 13 years, of $0.52 \%$.

Table (i). Population of Saint Lucia, 2001 - 2014

| Item | Total Population |  |
| :--- | :---: | :---: |
| Census 2001 | 156,733 |  |
| 2001 | Mid-year 2001-2009 | 156,841 |
| 2002 |  | 157,831 |
| 2003 | 158,815 |  |
| 2004 | 159,805 |  |
| 2005 | 160,791 |  |
| 2006 |  | 161,780 |
| 2007 | 162,766 |  |
| 2008 | 163,756 |  |
| 2009 |  | 164,743 |
| Census 2010 | 165,591 |  |
|  |  |  |
| 2010 |  | 165,691 |
| 2011 | 166,298 |  |
| 2012 | 166,773 |  |
| 2013 | 167,292 |  |
| 2014 | 167,769 |  |
| Absolute Increase | 10,928 |  |
| Percentage Increase | 7.0 |  |
| Average annual rate of growth (\%) | 0.52 |  |

Population growth is a function of the three components of change: births, deaths and migration. These events can add or take away from the population. The low population growth rates observed for Saint Lucia must be interpreted within the context of changes in these three components over the period. Table (ii) presents the components of population growth for the intercensal period from 2001-2009 and for the individual years between 2010 and 2014 in the postcensal period. The table shows an average annual rate of growth overall of $0.6 \%$ in the intercensal years, due largely to the number of births recorded, 25,614 , with the resulting birth rate of 17.7 per 1,000 . For the years following, the growth rate was cut by one-half as the average crude birth rate fell to about 13
per 1,000 . While migration was reduced with the rate dropping from -5 per 1,000 to -2.3 per 1,000 , death rates remained stable at about 7 per 1,000 .

Table (ii). Summary of Population Movements and Components of Growth for Saint Lucia, 2001-2014

| Mid-Year | Population | Births, Deaths and Migration in Period |  |  |  |  |  |  |  | Annual <br> (\%) <br> Growth <br> Rate |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Sex Composition

Of the total estimated 2014 population of 167,769 , females numbered 84,463 and males 83,306 . As seen in table (iii) this represents an almost equal distribution of men and women in the population. Between 2001 and 2014, the male population grew much faster $(8.5 \%)$ than the female population $(5.5 \%)$. This showed a considerable drop in the excess of women over men from 3,338 in 2001 to 1,157 in 2014. The outcome was an increase in the sex ratio (the number of males per 100 females) from 95.8 per 100 in 2001 to 98.6 in 2014.

Table (iii). Sex Composition of the Population, 2001 and 2014

|  | 2001 |  | 2014 |  |
| :--- | :---: | :---: | :---: | :---: |
| Item | No of | Percent | No of | Percent |
| Total | 156,840 | 100 | 167,769 | 100 |
| Male | 76,751 | 48.9 | 83,306 | 49.7 |
| Female | 80,089 | 51.1 | 84,463 | 50.3 |
| Excess of Females/Males | 3,338 |  | 1,157 |  |
| Sex Ratio | 95.8 |  | 98.6 |  |
|  | Change between 2001 and 2014 |  |  |  |
|  | Absolute |  | Annual Rate of Growth |  |
|  | Change | Percentage Change | (\%) |  |
| Total | 10,929 | 7.0 | 0.52 |  |
| Male | 6,555 | 8.5 | 0.63 |  |
| Female | 4,374 | 5.5 | 0.41 |  |

## Age Structure

Changes resulting from declining fertility and improved mortality conditions have led to distinctive changes in the age structure. Table (iv) shows the distribution of the population in specific age groups and the changes between 2001 and 2014. The information presented in the table reflects the decline in fertility previously noted, as shown by the reduction in the youngest age groups. Indications of an ageing population are also evident as the proportion of the oldest ages increased.

At mid-year 2014, the number of people under age 15 years numbered approximately 42,000 or $25 \%$ of the total population. This represents a decline in numbers of nearly 6,000 persons when compared with the 2001 population. At 2014, the youth population ages 15-29 years totaling about 43,000 persons accounted for onequarter of the population and showed a very small increase over 2001, of 259 . The prime working age population of ages 30-64 years increased by $27.6 \%$ from 53,797 in 2001 to 68,650 by 2014 and accounted for about $41 \%$ of the total population up from $34.3 \%$. The large growth in this age group is primarily attributable to the ageing of the survivors of the high fertility periods of the past thirty to forty years.

Table (iv). Distribution of the Population for Specific Age Groups, 2001 and 2014

|  | 2001 |  | 2014 |  | Change 2001-2014 |  |
| :--- | :---: | :---: | :---: | :---: | :---: | ---: |
| Selected Age Groups | Number | Percent | Number | Percent | Number | Percent |
| Under 15 years | 47,926 | 30.6 | 41,973 | 25.0 | $-5,953$ | -12.4 |
| $15-29$ years | 42,594 | 27.2 | 42,853 | 25.5 | 259 | 0.6 |
| $30-64$ | 53,797 | 34.3 | 68,650 | 40.9 | 14,853 | 27.6 |
| 65 years and over | 12,524 | 8.0 | 14,293 | 8.5 | 1,769 | 14.1 |
| Total | 156,841 | 100.0 | 167,769 | 100.0 | 10,928 | 7.0 |

Occurring simultaneously with the decreases among the youngest age groups are increases among the oldest, the 65 years and over. An estimated 1,800 persons were added to this age group over the period, taking the proportion of the total population from $8 \%$ to approximately $9 \%$.

The changing age profile is best observed graphically as presented in the age sex population pyramid shown as figure 1. Each horizontal bar of the pyramid represents the size of an age-sex group. The bottom bar shows the number of males and females who are of ages $0-4$ years at the date. The short bars at the top of the pyramid shows the small number of survivors of the oldest birth cohorts. Each year a new cohort is born and forms the base of the pyramid while those above move up. As the cohorts age they inevitably lose members to deaths and migration.

Figure 1. Age-Sex Pyramid for Saint Lucia at 2001 (shaded) and 2014
Males
Females

The pyramids presented reflect the age distribution for 2001 (shaded) superimposed on the pyramid based on the structure for 2014 (unshaded). The narrowing of the horizontal bars at the base of the pyramids is directly related to the decline in the number of persons at the young ages, resulting mainly from the fertility declines. The wider unshaded bars higher up the pyramid are based on the increases after age 30 years, as discussed.

The sex ratios presented for broad age groups in table 5 show the excess of men among the youngest with a reversed pattern in the oldest age groups. Up to age 24 years there are about 103 men to 100 women. At ages 75 years and over the ratio is reduced considerably and by that age there are about 72 men to 100 women. The excess of males seen for the age group 45-54 years is likely an indication of the pattern of modern migratory movements where females are predominant. The high excess of females among the oldest is indicative of the higher mortality rates for men.

Table (v). Age-Sex Population Profile, 2014

|  | Population in thousands |  |  |
| :--- | :---: | :---: | :---: |
| Age Group | Male | Female | Sex Ratio* |
| Under 15 | 21.3 | 20.6 | 103.4 |
| $15-24$ | 14.9 | 14.6 | 102.1 |
| $25-34$ | 12.7 | 12.8 | 99.4 |
| $35-44$ | 12.0 | 12.5 | 96.0 |
| $45-54$ | 10.0 | 9.9 | 100.2 |
| $55-64$ | 5.9 | 6.1 | 96.2 |
| $65-74$ | 3.8 | 4.2 | 91.7 |
| 75 and over | 2.6 | 3.7 | 71.6 |
| Total | $\mathbf{8 3 . 3}$ | $\mathbf{8 4 . 5}$ | $\mathbf{9 8 . 6}$ |

The age distribution of the population forms the basis for an examination of dependency ratios. The variations in the proportions of children, the elderly and persons of working age are taken account of jointly in this indicator. The age dependency ratio represents the ratio of the child population and the old age population combined, the dependent ages (under 15 years and 65 years and over), to the population of the economically productive (15-64 years). Table (vi) presents the population in broad age groups and the dependency ratios for 2001 and 2014.

Table (vi). Population by broad age groups and Dependency Ratios,* 2001 and 2014

|  | Population |  |  |
| :--- | :---: | :---: | :---: |
| Age Group | 2001 | 2014 | Total change 2001-2014 |
| Under 15 | 47,926 | 41,973 | $-5,953$ |
| $15-44$ | 75,018 | 79,630 | 4,612 |
| $45-64$ | 21,373 | 31,873 | 10,500 |
| 65 years and over | 12,524 | 14,293 | 1,769 |
| Total | 156,841 | 167,769 | $\mathbf{1 0 , 9 2 8}$ |
| Item | 2001 | 2014 | \% change 2001-2014 |
| Child Dependency Ratio | 49.7 | 37.6 | -24.3 |
| Old Age Dependency Ratio | 13.0 | 12.8 | -1.3 |
| Total Dependency Ratio | 62.7 | 50.5 | -19.5 |

*per 100 population $15-64$ years old

In 2001, for every 100 persons of working age there were approximately 63 in the 'dependent' group. By 2014 this ratio had fallen by about $20 \%$ to 51 . The child dependency ratio which relates the population less than 15 years old to the population 15-64 years old fell from 49.7 per 100 to 37.6 per 100 between 2001 and 2014. The old age ratio, which relates the 65 years and over population to that 15-64 years old, remained unchanged at about 13 per 100. The changes over the period must be interpreted within the context of the overall changes in the size of the population in the relevant age groups. The large increase of over 15,000 in the 15-64 years age group occurs simultaneously with the decline of about 6,000 for the youngest and a relatively small increase of about 1,800 in the 65 years and over age group.

## District Profile

## Size and Growth of Districts

Intercensal and postcensal estimates of the population of the 10 districts in Saint Lucia are based on an assumption of a constant proportional distribution of the census proportions. This analysis is based on observations from the census data.

Nine of the 10 districts experienced growth of varying degrees and one declined over the period (table (vii)). The fastest growing district between 2001 and 2010 was the northern district of Gros Islet. The population of Gros Islet grew by $22 \%$ over the period, three times the growth observed for the country as a whole. Following Gros Islet, the fastest growing districts were Canaries, Soufriere and Vieux Fort. Canaries and Soufriere each grew by $14 \%$ and Vieux Fort by $10 \%$. In terms of actual numbers, the district of Gros Islet grew by approximately 4,600 between 2001 and 2010, thereby contributing more than one half ( $52 \%$ ) of the total growth of the country. Vieux

Fort, Castries and Soufriere contributed $17 \%, 15 \%$ and $11 \%$ respectively of the total growth. One district, Laborie declined in population, by about $10 \%$.

Table (vii). Population by District, 2001 and 2010

|  | Population |  | Change 2001-2010 |  | \% of Total <br> Growth |
| :--- | ---: | ---: | ---: | ---: | ---: |
| District | 2001 | Number | $\%$ |  |  |
| Castries | 63,355 | 64,662 | 1,307 | 2.1 | 14.8 |
| Anse-La-Raye | 6,313 | 6,373 | 60 | 1.0 | 0.7 |
| Canaries | 1,770 | 2,013 | 243 | 13.7 | 2.7 |
| Soufriere | 7,418 | 8,432 | 1,014 | 13.7 | 11.5 |
| Choiseul | 6,080 | 6,120 | 41 | 0.7 | 0.5 |
| Laborie | 7,242 | 6,535 | -707 | -9.8 | -8.0 |
| Vieux Fort | 15,136 | 16,643 | 1,507 | 10.0 | 17.0 |
| Micoud | 15,736 | 16,448 | 712 | 4.5 | 8.0 |
| Dennery | 12,409 | 12,489 | 80 | 0.6 | 0.9 |
| Gros Islet | 21,274 | 25,875 | 4,601 | 21.6 | 51.9 |
| Total | $\mathbf{1 5 6 , 7 3 3}$ | $\mathbf{1 6 5 , 5 9 1}$ | $\mathbf{8 , 8 5 8}$ | 5.7 | $\mathbf{1 0 0 . 0}$ |

Despite these changes, the share of the total population for each district did not shift sufficiently to change the ranking. Table (viii) and figure 2 show that in 2010 as in 2001, Castries remained the most populous district followed by Gros Islet. At the 2010 census Castries accounted for $39 \%$ of the total population of Saint Lucia, a slip down by one percentage point from the $40 \%$ share in 2001. Gros Islet remained at number two despite the strong growth discussed, accounting for approximately $16 \%$ of the total, up from $14 \%$ in 2001. The combined share of $54 \%$ by Castries and Gros Islet indicates that more than one half of the population of Saint Lucia live in the northern section of the island. The districts of Vieux Fort and Micoud remained very close in terms of percentage share with about $10 \%$ each. At the other end of the spectrum is Canaries, the least populated district, with a share of only $1 \%$ of the total population. Of interest, is the fact that despite the decline in population over the period, Laborie retained its position at number seven in the ranking of districts by population size.

Table (viii). Percentage distribution of the Population by Districts, 2001 and 2010

|  |  |  |  |
| :--- | :---: | :---: | :---: |
| District | \% Share of total population | Change in percentage points |  |
| Castries | 2001 | 2010 | $2001-2010$ |
| Anse-La-Raye | 40.4 | 39.0 | -1.37 |
| Canaries | 4.0 | 3.8 | -0.18 |
| Soufriere | 1.1 | 1.2 | 0.09 |
| Choiseul | 4.7 | 5.1 | 0.36 |
| Laborie | 3.9 | 3.7 | -0.18 |
| Vieux Fort | 4.6 | 3.9 | -0.67 |
| Micoud | 9.7 | 10.1 | 0.39 |
| Dennery | 10.0 | 9.9 | -0.11 |
| Gros Islet | 7.9 | 7.5 | -0.38 |
| Total | 13.6 | 15.6 | 2.05 |

Figure 2. Percentage Distribution of the Population by Districts at Censuses 2001 and 2010

## Sex Composition of Districts

The sex composition of the district populations at census 2010 is the subject of table (ix). Females outnumbered males in all but four districts. The five districts with high sex ratios (more than 100 men per 100 women) were Anse-La Raye ( 105.6 per 100), Canaries (105.5 per 100), Soufriere ( 103.9 per 100), Vieux Fort (102.3 per 100), and Dennery ( 100.6 per 100). The sexes were equally balanced in Micoud while females outnumbered males in the remaining four districts. The lowest sex ratio ( 93.3 per 100) is observed for Gros Islet followed by Castries ( 97.5 per 100), Choiseul ( 99.1 per 100) and Laborie ( 99.3 per 100). Despite the fact that men outnumbered women in the majority of districts the excesses were far less than the deficits resulting in an overall sex ratio of 98.6 per 100.

Table (ix). Analysis of the Sex Composition by Districts, 2010

| District | Excess/Deficit of Males |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Male | Female | over Females* | Sex Ratio |
| Castries | 31,929 | 32,733 | -804 | 97.5 |
| Anse-La-Raye | 3,273 | 3,101 | 172 | 105.6 |
| Canaries | 1,034 | 980 | 54 | 105.5 |
| Soufriere | 4,297 | 4,135 | 162 | 103.9 |
| Choiseul | 3,047 | 3,073 | -26 | 99.1 |
| Laborie | 3,256 | 3,279 | -24 | 99.3 |
| Vieux Fort | 8,417 | 8,225 | 192 | 102.3 |
| Micoud | 8,223 | 8,225 | -2 | 100.0 |
| Dennery | 6,263 | 6,227 | 36 | 100.6 |
| Gros Islet | 12,486 | 13,389 | -903 | 93.3 |
| Total | 82,224 | 83,367 | -1,144 | 98.6 |
| Total excess of males |  |  | 616 |  |
| Total deficit of males |  |  | -1759 |  |

## Age Structure of Districts

The previous discussion on age structure for the population of Saint Lucia focused on the population pyramid. It is useful to examine the age structure of the district populations within the context of the changes which have been discussed. Such changes have resulted from declining fertility levels and improved mortality conditions. One indicator which may be examined is the median age of the population. The median age is that age which divides a population into numerically equal parts of younger and older persons.

Table (x). Median Age of the Population by Districts, 2001 and 2010

| District | Median Age in years |  | Years added |
| :--- | :---: | :---: | :---: |
|  | 2001 | 2010 | $2001-2010$ |
| Castries | 25.7 | 30.0 | 4.3 |
| Anse-La-Raye | 22.7 | 27.2 | 4.5 |
| Canaries | 25.0 | 29.9 | 4.9 |
| Soufriere | 25.1 | 28.9 | 3.9 |
| Choiseul | 27.5 | 31.8 | 4.3 |
| Laborie | 24.4 | 30.0 | 5.6 |
| Vieux Fort | 23.4 | 27.8 | 4.4 |
| Micoud | 23.4 | 28.1 | 4.7 |
| Dennery | 23.2 | 27.9 | 4.7 |
| Gros Islet | 27.6 | 32.3 | 4.7 |
| Total | $\mathbf{2 5 . 2}$ | $\mathbf{2 9 . 6}$ | $\mathbf{4 . 4}$ |

Median ages for the total population of each district at the censuses of 2001 and 2010 and the number of years of age added over the period are presented in table (x). The median age for the country as a whole was 29.6 years at 2010, having risen by 4.4 years from 25.2 years at 2001. The district with the oldest population at 2010 was Gros Islet ( 32.3 years) and the district with the youngest at that date was Anse-La-Raye ( 27.2 years). The district of Laborie, the sole district which experienced a decrease in population over the period had the largest additions to median age, 5.6 years, from 24.4 years in 2001 to 30.0 years in 2010.

As was done for the country as a whole, an analysis of the age structure of the districts may be extended to the examination of age dependency ratios. Table (xi) shows the percentage distribution of each of the three age groups relevant to the calculation of dependency ratios, for the districts, for 2001 and 2010. Movements in the age groups reflecting an ageing of the population for the country as a whole has been previously discussed. All districts reflect reductions in the population of ages 0-14 years, and the resulting child dependency ratios. Anse-La-Raye, the district with the lowest median age, had the highest proportion of this age group (28.3\%) at 2010, down from $34.6 \%$ at 2001 . For Gros Islet, the district with the oldest population, the proportion of the young population moved from $27.6 \%$ to $22.8 \%$, the lowest of all districts at both dates. This pattern is reflected in the child dependency ratios for these districts. Anse-La-Raye had the highest child dependency ratio at both dates. For this district, there were approximately 45 young dependents per 100 persons of working age at 2010 down from about 60 per 100 at 2001.

Table (xi). Percentage of District Population in Specific Age Groups and Dependency Ratios, 2001 and 2010

| District | Percentage of Population |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Under 15 years |  | 15-64 years |  | 65+ years |  |
|  | 2001 | 2010 | 2001 | 2010 | 2001 | 2010 |
| Castries | 29.2 | 24.6 | 63.2 | 67.4 | 7.6 | 8.0 |
| Anse-La-Raye | 34.6 | 28.3 | 57.3 | 63.4 | 8.1 | 8.3 |
| Canaries | 32.1 | 24.9 | 57.2 | 64.9 | 10.7 | 10.1 |
| Soufriere | 31.5 | 26.0 | 59.3 | 64.8 | 9.2 | 9.2 |
| Choiseul | 31.0 | 24.7 | 56.1 | 62.5 | 12.9 | 12.9 |
| Laborie | 32.1 | 23.9 | 58.3 | 65.8 | 9.6 | 10.3 |
| Vieux Fort | 33.4 | 26.9 | 60.2 | 65.6 | 6.4 | 7.5 |
| Micoud | 32.8 | 25.9 | 58.8 | 64.8 | 8.4 | 9.3 |
| Dennery | 33.6 | 26.5 | 58.5 | 64.7 | 7.9 | 8.8 |
| Gros Islet | 27.6 | 22.8 | 65.3 | 69.1 | 7.2 | 8.0 |
| Total | 30.6 | 25.0 | 61.4 | 66.5 | 8.0 | 8.5 |
|  | Dependency Ratio |  |  |  |  |  |
|  | Child |  | Old Age |  | Total |  |
| Castries | 46.1 | 36.5 | 12.1 | 11.9 | 58.2 | 48.4 |
| Anse-La-Raye | 60.4 | 44.7 | 14.1 | 13.0 | 74.5 | 57.7 |
| Canaries | 56.1 | 38.4 | 18.7 | 15.6 | 74.8 | 54.0 |
| Soufriere | 53.0 | 40.2 | 15.6 | 14.2 | 68.6 | 54.4 |
| Choiseul | 55.4 | 39.5 | 23.0 | 20.6 | 78.4 | 60.1 |
| Laborie | 55.1 | 36.3 | 16.4 | 15.7 | 71.5 | 52.0 |
| Vieux Fort | 55.4 | 41.0 | 10.6 | 11.5 | 66.0 | 52.4 |
| Micoud | 55.8 | 39.9 | 14.3 | 14.4 | 70.1 | 54.3 |
| Dennery | 57.3 | 40.9 | 13.5 | 13.7 | 70.9 | 54.6 |
| Gros Islet | 42.2 | 33.0 | 11.0 | 11.6 | 53.2 | 44.6 |
| Total | 49.9 | 37.6 | 13.0 | 12.8 | 62.9 | 50.5 |

## APPENDIX B

# PROCEDURES FOR CALCULATION OF POPULATION ESTIMATES 

## METHODOLOGY

The methodology used to derive the series of estimates of the population presented in this report was the component method. This method takes account of the components of population change: births, deaths and migration. In this procedure each component is estimated separately and is added to or subtracted from a base population to derive a population at some other date.

The basic formula for the component method is:
$P_{t}-P_{o}=B-D+I-E$
Where
$P_{t}=$ the population at the end of the period
$\mathrm{P}_{\mathrm{o}}=$ the population at the beginning of the period
B = births
$\mathrm{D}=$ deaths
I = immigration
$\mathrm{E}=$ emigration
As indicated in the introduction, an important aspect of population estimation is determining the definition of the base population which may be either 'de jure' or 'de facto'. Censuses of population and housing for Saint Lucia have historically been conducted on a de facto basis. This means that all persons on the island at the date designated census day are included in the count as presented. The first census to be conducted on the de jure basis was 2010. The de jure count excludes persons on the island who are not usual residents while including all usual residents temporarily away from the island.

In order to present a smooth consistent series for 2001-2014 the de jure count from census 2001 is used as the base. The guiding principle in preparing population estimates is always to maintain consistency between the population totals and the change components of births, deaths and migration.

## DATA AVAILABILITY AND DEFICIENCIES

A major challenge in the estimation of population estimates for Saint Lucia in recent years has been the lack of access to the records of the Civil Registry for the collection of the basic vital statistics. The last year for which data are available is 2014. This restriction and the attempt to tap into other sources is reflected in the notes to the data tables received for the purposes of this project:

- Births and deaths statistics prior to 2008 - Civil Registry
- Births for 2008-2012 - Epidemiology Unit of the Ministry of Health
- Mortality data for 2008-2009 - Epidemiology Unit of the Ministry of Health
- Mortality data for 2010-2012 - Civil Registry
- Births and Deaths since 2012 - Epidemiology Unit of the Ministry of Health

The available data from these different sources for the series being presented in this report were:

- Births by sex 1990-2014
- Births by sex and age of mother 2001-2014
- Deaths by sex 1990-2014
- Deaths by age and sex 2001-2014

In a number of cases there were inconsistencies between the totals of births and deaths by sex and the totals by age. In such cases, the data by age of mother (births) and age of deceased (deaths) were used.

While series of registered births and deaths are available, no series exist for migration. As is typical for most countries, estimates of this component are generally derived as a residual after births and deaths are accounted for.

## PROCEDURAL STEPS

## Step 1: Estimating the Components of Change 2001-2010

An evaluation of the components is done by an examination of the changes in the age structure between the two censuses. The examination of the age data is done separately for two broad age groups representing the population alive at the earlier census (the ages 10 years and over is used as a convenient separation point, especially for decennial censuses) and the population born during the intercensal period (the population of less than 10 years old at the later census). This latter group is expected to be the survivors of the births occurring over the period. Survivors in this sense would be those remaining after deaths and any migration. With an intercensal period of approximately 9 years, the population 10 years and over at census 2010 was 1 year old and over at 2001. This population would have aged 9 years representing the interval between the two censuses. During the interval there would be decrements due to deaths and emigration and additions from immigration only. Births which occur during the 9 years would have no effect on this age group.

## a. Estimating intercensal deaths from full year deaths registered 2001-2010

Table B1.1. Registered deaths by broad age groups, 2001-2010

| Age group | Male | Female | Total |
| :--- | ---: | ---: | ---: |
| Under 10 years | 282 | 252 | 534 |
| $10+$ years | 5,494 | 4,431 | 9,925 |
| Total | $\mathbf{5 , 7 7 6}$ | $\mathbf{4 , 6 8 3}$ | $\mathbf{1 0 , 4 5 9}$ |

The number of deaths to persons aged 1 and over at the earlier census is derived by adding together the deaths at ages 1 and over in the census year, those at ages 2 and over in the following year, those at ages 3 and over next and so on until the 2010 census when those at ages 10 and over are added. Deaths for single years are derived from the 5 -year age groups by interpolation using BEERS Ordinary Interpolation. Using the registered deaths by age for the years 2001-2010, the changes due to the deaths and the residual accepted as migration appear below for males and females separately, for all ages 10 years old and over at census 2010.

Table B1.2. Change in Population between May 22, 2001 and May 10, 2010 from deaths and migration for ages 10 years and over

| Age at census 2001 | Age at census 2010 | Population at census 2001 (original count) | Population at census 2010 (original count) | Total Change | Deaths | Imputed <br> Migration |

| 16-20 | 25-29 | 8,236 | 6,725 | -1,511 | -68 | -1,443 |
| 21-25 | 30-34 | 6,620 | 6,081 | -539 | -76 | -463 |
| 26-30 | 35-39 | 6,627 | 6,317 | -310 | -88 | -222 |
| 31-35 | 40-44 | 6,167 | 6,176 | 9 | -93 | 102 |
| 36-40 | 45-49 | 5,794 | 5,459 | -335 | -115 | -220 |
| 41-45 | 50-54 | 4,403 | 4,472 | 69 | -109 | 178 |
| 46-50 | 55-59 | 3,405 | 3,308 | -97 | -144 | 47 |
| 51-55 | 60-64 | 2,781 | 2,789 | 8 | -205 | 213 |
| 56-60 | 65-69 | 2,472 | 2,291 | -181 | -269 | 88 |
| 61-65 | 70-74 | 2,154 | 1,863 | -291 | -303 | 11 |
| 66-70 | 75-79 | 1,818 | 1,425 | -393 | -411 | 18 |
| 71+ | 80+ | 4,609 | 2,257 | -2,352 | -1,974 | -378 |
| Total |  | 79,450 | 71,166 | -8,284 | -3,995 | -4,289 |

In order to complete the total decrements from deaths and migration between 2001 and 2010, the next step is to derive the estimates of these components for the younger population. As was outlined previously, deaths for the population 10 years and over at 2010, 9 years after 2001, began with an accounting of deaths of those aged 1 year and over in 2001, 2 years and over in 2002, 3 years and over in 2004 and so on. The deaths excluded for that group represent deaths for the ages $0-9$ years at 2010. The final count of intercensal deaths for the two broad age groups is shown in table B1.3.

## Table B1.3. Final intercensal deaths by broad age groups and sex

| Item | Male | Female | Total |
| :--- | ---: | ---: | ---: |
| Deaths to population 10 years and over at 2010 | 4,960 | 3,995 | 8,955 |
| Deaths to population 0-9 years at 2010 | 231 | 223 | 454 |
| Grand Total Deaths | $\mathbf{5 , 1 9 1}$ | $\mathbf{4 , 2 1 8}$ | $\mathbf{9 , 4 0 9}$ |

## b. Estimating migration for the population 0-9 years old at census 2010

(References for Methodology: Siegel, Jacob and Swanson, David - The Methods and Materials of Demography, page 507 and Rowlands, Donald T. Demographic Methods and Concepts, page 410).

Losses from migration for the population 0-9 years old are calculated by relating the child/woman ratio separately for the $0-4$ and $5-9$ years groups to the estimate of migration for the women of childbearing ages. This method assumes that the children were born before their mothers migrated. The assumption is that migration occurs evenly over the intercensal period and that one quarter of the younger and three quarters of older children were born before their mothers migrated.

The method relates the child/woman ratio to female migrants as follows:
Table B1.4. Base data for calculating migration of population 0-9 years at census 2010

|  | Sex of Child |  | Child/Woman Ratio* |  |
| :--- | :---: | :---: | :---: | :---: |
| Age of Child | Male | Female | Female |  |
| $0-4$ | 6,050 | 5,763 | 0.151595 | 0.144404 |
| $5-9$ | 6,709 | 6,438 | 0.17835 | 0.171146 |
| Age of Woman | Number of Women |  | Women Migrants |  |
| $15-44$ | 39,909 |  | $-3,812$ |  |
| $20-49$ |  | 37,617 | $-3,588$ |  |

Source: number of children and women from census data; migrants from table B1.2.
*(child 0-4/women 15-44); (child 5-9/women 20-49) from 2010 census
Migration of 0-4 years $=.25 *$ child/woman ratio*migration of females $15-44=-144$ males, -138 females
Migration of 5-9 years $=.75 *$ child/woman ratio*migration of females $20-49=-480$ males, -461 females
Total Migration 0-9 years $=-624$ males, -599 females
The resulting migration appears in table B 1.5 with the migration estimated previously for the older age group.
Table B1.5. Final intercensal migration by broad age groups and sex

| Item | Male | Female | Total |
| :--- | ---: | ---: | ---: |
| Migration of population 10 years and over at 2010 | $-1,737$ | $-4,289$ | $-6,026$ |
| Migration of population 0-9 years at 2010 | -624 | -599 | $-\mathbf{- 1 , 2 2 3}$ |
| Grand Total Migration | $\mathbf{- 2 , 3 6 1}$ | $\mathbf{- 4 , 8 8 8}$ | $\mathbf{- 7 , 2 4 9}$ |

## Table B1.6. Final intercensal components by sex

| Item | Male | Female | Total |
| :--- | ---: | ---: | ---: |
| Census May 22 2001 count | 76,683 | 80,050 | 156,733 |
| Deaths to population 10+ years at census 2010 | 4,960 | 3,995 | 8,955 |
| Deaths to population under 10 years at census 2010 | 231 | 223 | 454 |
| Total Deaths | 5,191 | 4,218 | 9,409 |
| Migration of population 10+ years at census 2010 | $-1,737$ | $-4,289$ | $-6,026$ |
| Migration of population under 10 years at census 2010 | -624 | -599 | $-1,223$ |
| Total Migration | $-2,361$ | $-4,888$ | $-7,249$ |
| Population minus births | 69,131 | 70,944 | 140,075 |
| Census 2010 count | 82,224 | 83,367 | 165,591 |
| Births required | 13,093 | 12,423 | 25,516 |
| Original Births | 10,535 | 10,082 | 20,617 |

The final intercensal components after accounting for decrements are shown in table B1.6. The table also shows the population after decrements and the total number of births required in order to attain the population count for 2010, almost 5,000 more than the number recorded as registered over the period. Table B1.7 shows the adjustments made to the original births to obtain the revised total.

Table B1.7. Revision of intercensal births

| Year | Original Births |  | Revised Births* |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Male | Female | Male | Female |
| 2000 | 1,406 | 1,498 | 1,406 | 1,498 |
| 2001 | 1,405 | 1,383 | 1,746 | 1,704 |

[^0]
## Step 2 Adjusting the 2010 census population for age

An important consideration in the process of adjusting census data years after the censuses have been completed and results published is that the census totals cannot be changed. Any adjustments made are for the purposes of analysis and to maintain a smooth series of intercensal and postcensal estimates. The final step in the adjustment process is one which is done to maintain the original census total.

## a. Estimating the population 0-9 years old at census 2010 from births

A basic first check in the assessment of the age distribution at the census is that involving the younger of the two age groups previously identified: the population born after the earlier census, that is the population under 10 years old. It is this age group which generally is subject to the highest levels of under enumeration.

The population under 10 years old at census 2010 is expected to be the survivors of the births occurring between May 11, 2000 and May 102010 (table B2.1).

Table B2.1. Age at census 2010 and the relevant birth cohorts, 2000-2010

| Age at May 10 2010 <br> (census day) | Birth date |  |
| :---: | :---: | :---: |
|  | May 11 to December 31 of year | January 1-to May 10 of year |
| 1 | 2009 | 2010 |
| 2 | 2008 | 2009 |
| 3 | 2007 | 2008 |
| 4 | 2006 | 2007 |
| 5 | 2005 | 2006 |
| 6 | 2004 | 2005 |
| 7 | 2003 | 2004 |
| 8 | 2002 | 2003 |
| 9 | 2001 | 2002 |

Note: Registrations represent calendar year, revised from table B1.7. Fraction of year's events for January 1 to May 10 of each year $=130 / 365=.3562$ and for May 11-December $31=235 / 365=.6438$. For example, population at age 2 years at census $2010=$ births between May 11 and December 31, 2007 (estimated as .6438 of that year's births) plus births between January 1 and May 10, 2008 (estimated as .3562 of that year's births).

Table B2.2. Revised population 0-9 years at census 2010

| Item | Male | Female |
| :--- | ---: | ---: |
| Total Births 2000-2010 | 15,914 | 15,343 |
| Of which survivors of birth cohorts | 14,678 | 14,050 |
| Deaths 0-9 years | 240 | 229 |
| Migration 0-9 years | 624 | 599 |
| Final population 0-9 years | 13,814 | 13,223 |
| Of which |  |  |
| Age 0-4 | 6,695 | 6,397 |
| Age 5-9 | 7,119 | 6,826 |

Table B2.3. Final adjusted population for census 2010

|  | Census after adjusting 0-9 |  |  |  |  |  |

| $40-44$ | 6,040 | 6,176 | 6,040 | 6,176 | 5,964 | 6,101 |
| $45-49$ | 5,499 | 5,459 | 5,499 | 5,459 | 5,429 | 5,393 |
| $50-54$ | 4,454 | 4,472 | 4,454 | 4,472 | 4,398 | 4,418 |
| $55-59$ | 3,183 | 3,308 | 3,183 | 3,308 | 3,143 | 3,268 |
| $60-64$ | 2,689 | 2,789 | 2,689 | 2,789 | 2,655 | 2,755 |
| $65-69$ | 2,083 | 2,291 | 2,083 | 2,291 | 2,057 | 2,263 |
| $70-74$ | 1,730 | 1,863 | 1,730 | 1,863 | $\mathbf{1 , 7 0 8}$ | 1,840 |
| $75-79$ | 1,150 | 1,425 | 1,150 | 1,425 | $\mathbf{1 , 1 3 5}$ | 1,408 |
| $80+$ | 1,486 | 2,257 | 1,486 | 2,257 | $\mathbf{1 , 4 6 7}$ | 2,230 |
| Total | $\mathbf{8 2 , 2 2 4}$ | $\mathbf{8 3 , 3 6 7}$ | $\mathbf{8 3 , 2 7 7}$ | $\mathbf{8 4 , 3 8 9}$ | $\mathbf{8 2 , 2 2 4}$ | $\mathbf{8 3 , 3 6 7}$ |

Adjustment factor $=$ original population/first adjusted population $=$ males $=.98736$ females $=.98789$

## Step 3 Adjusting the 2001 population census for age

## a. Estimating the population 0-9 years old at census 2001 from births

The population under 10 years old at census 2001 represent the survivors of the births occurring between May 23, 1991 and May 22, 2001 (table B3.2).

Table B3.2. Age at census 2001 and the relevant birth cohorts, 1991-2001

| Age at May 222001 (census day) | Birth Date |  |
| :---: | :---: | :---: |
|  | From May 23 to December 31 of year | From January 1 to May 22 of year |
|  | 2000 | 2001 |
| 1 | 1999 | 2000 |
| 2 | 1998 | 1999 |
| 3 | 1997 | 1998 |
| 4 | 1996 | 1997 |
| 5 | 1995 | 1996 |
| 6 | 1994 | 1995 |
| 7 | 1993 | 1994 |
| 8 | 1992 | 1993 |
| 9 | 1991 | 1992 |

Note: Registrations represent calendar year. Fraction of year's events for January 1 to May 22 of each year = 142/365 days = .3890 and for May 23-December $31=225 / 365$ days $=.6110$. For example, population at age 9 years at census $2001=$ births between May 11 and December 31, 1991 (estimated as .6110 of that year's births) plus births between January 1 and May 22, 1992 (. 3890 of that year's births).

Table B3.3. Registered births, 1991-2001

|  | Births |  |
| :---: | :---: | :---: |
| Year | Male | Female |
| 1991 | 1,943 | 1,809 |
| 1992 | 1,950 | 1,811 |
| 1993 | 1,810 | 1,746 |
| 1994 | 1,897 | 1,787 |
| 1995 | 1,936 | 1,769 |
| 1996 | 1,628 | 1,671 |
| 1997 | 1,768 | 1,676 |
| 1998 | 1,506 | 1,444 |
| 1999 | 1,497 | 1,500 |
| 2000 | 1,406 | 1,498 |
| 2001 | 1,405 | 1,383 |

Table B3.4. Population 0-9 years at census 2001 estimated from births

| Item | Male | Female |
| :--- | :---: | :---: |
| Total births 1991-2001 | 18,746 | 18,094 |
| Population from births at 2001 at age: |  |  |
| 0 | 1,406 | 1,453 |
| $1-4$ | 6,313 | 6,224 |
| $0-4$ | 7,719 | 7,677 |
| $5-9$ | 9,413 | $\mathbf{8 , 8 6 8}$ |
| Total 0-9 | $\mathbf{1 7 , 1 3 2}$ | $\mathbf{1 6 , 5 4 5}$ |

Derived by applying fraction of year to number of births shown in table B3.3.

## b. Estimating survivors of birth cohorts for 0-9 years

This is done by applying survival ratios from life tables. Survival ratio for age 0 calculated from life table for year 2000 with life expectancy of 70.2 years for men and 74.1 years for women. Survival ratio for ages 1-9 calculated from around 1990 life table with life expectancy of 69.3 years for men and 73.1 years for women.

Survival ratio for age $0=\mathrm{Lo} / \mathrm{lo}$
Survival ratio for $1-4$ years $=4 \mathrm{~L} 1 / 4$ (lo)
Survival ratio for 5-9 years $=5 \mathrm{~L} 0 / 5(\mathrm{lo})$
Table B3.5. Survivors of 1991-2001 birth cohorts

| Item | Male | Female |
| :--- | :--- | :--- |
| Survival ratios for age: |  |  |
| 0 | .9849 | .9880 |
| $1-4$ | .9780 | .9793 |
| $5-9$ | .9744 | .9764 |
| Population after deaths at age |  |  |
| $0-4$ | 7558 | 7531 |
| $5-9$ | 9172 | 8659 |

## c. Estimating migration for 0-9 years old at census 2001

As calculated previously for 2010
Migration of 0-4 years $=.25 *$ child $/$ woman ratio* migration of females 15-44
Migration 5-9 years $=.75 *$ child $/$ woman ratio*migration of females 20-49

## d. Calculating child-woman ratio 2001

Table B3.6. Child-woman ratio by age and sex of child, 2001

| Age of Child | Number of Children |  |
| :---: | :---: | :---: |
|  | Male | Female |
| $5-9$ | 6,813 | 6,898 |
| Age of Women | 8,297 | 8,115 |
| $15-44$ | Number of Women |  |
| $45-49$ | 38,698 |  |
|  | Child/Woman Ratio |  |
| Age of Child | Male |  |
| $0-4$ | .176056 | Female |
| $5-9$ | .245619 | .178252 |

## e. Estimating migration for women

Migration for the intercensal period 1991-2001 was estimated by applying forward survival ratios to the population of the relevant ages at 1991 to obtain the expected count at census 2001. Backward survival ratios were applied to the 2001 count to derive an expected population at 1991. The difference between the actual and expected counts in both cases was imputed to migration. An average of the two migration estimates was used as the final estimate.

Table B3.7. Analysis of calculations for female migrants, 1991-2001

| Census 1991 |  | Forward Survival Ratio | Census 2001 |  |  | Assumed Migration |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Age | Population |  | Age | Actual Population | Expected Population |  |
| 5-34 | 41,414 | . 98928 | 15-44 | 38,698 | 40,970 | -2272 |
| 10-39 | 36,302 | . 98328 | 20-49 | 35,695 | 33,780 | -1915 |
| Census 2001 |  | Backward Survival Ratio | Census 1991 |  |  |  |
| Age | Population |  |  | Actual Population | Expected Population | Assumed Migration |
| 15-44 | 36,968 | 1.01084 | 5-34 | 41,414 | 39,118 | -2,296 |
| 20-49 | 35,695 | 1.01701 | 10-39 | 36,302 | 34,354 | -1,948 |
| Final Estimated Migration 1991-2001 |  |  |  |  |  |  |
| Age at Census 2001 | From Forward Survival Ratios | From Backward Survival Ratios | Average Migration |  |  |  |
| 15-44 | -2,272 | -2,296 | -2,284 |  |  |  |
| 20-49 | -1,915 | -1,948 | -1,931 |  |  |  |

Survival ratios calculated from life table calculated for 1990 with life expectancy of 69.3 years for men and 73.1 years for women. See glossary of terms and technical notes for explanation of survival ratios.

Forward survival ratio for 5-34 years in $1990=$ based on life table formula $n L x+t / n L x=(30 L 5+10 / 30 L 5)$
= 15L30/30L5
Backward survival ratio for $15-44$ years in $2001=$ based on life table formula $n L x-t / n L x(30 L 15-10 / 30 L 15)=30 L 5 / 30 L 15$

## f. Migration for 0-9 years calculated

Table B3.8. Final migration for 0-9 years at 2001

|  | Child/Woman Ratio |  |  |
| :---: | :---: | :---: | :---: |
| Age of Child | Male | Female | Female Migrants |
|  | .176056 | .178252 | -2284 |
| $5-4$ | .245619 | .240231 | -1931 |
| Age of Child | Migration of 0-9 |  |  |
| $0-4$ | -101 | -102 |  |
| $5-9$ | -356 | -348 |  |

## g. Final population 2001 census 0-9 years

Table B3.9. Revised population 0-9 years at census 2001

| Item | Male | Female |
| :--- | ---: | ---: |
| Total Births 1991-2001 | 18,746 | 18,094 |
| Of which survivors of birth cohorts | 17,132 | 16,545 |

Adjustment factor $=$ original population/first adjusted population $=$ males $=.98506$ females $=.99101$

## Step 4 Deriving intercensal mid-year population estimates for 2001-2009

Estimates were derived using the AGEINT spreadsheet which forms part of the PASEX workbooks developed for analyzing the age and sex composition of populations.

AGEINT interpolates between two age/sex distributions. The linear or exponential interpolation performed by this spreadsheet is made using the population in the same age groups at the two dates. The procedure assumes that the average annual change in each population age group has been constant during the intercensal period.

The linear interpolation is performed as follows:
$\mathrm{P}_{\mathrm{s}}=\mathrm{kP} \mathrm{P}_{\mathrm{i}}+(1-\mathrm{K}) \mathrm{P}_{\mathrm{j}}$
Where:
$P_{i}, P_{s}$, and $P_{j}$ represent the population of each age group at dates $\mathrm{i}, \mathrm{s}$, and j ;
s is the date for which the interpolation is desired (it must be chronologically between dates i and j ); and k is a constant for all age groups, calculated as:

$$
\mathrm{k}=(\mathrm{j}-\mathrm{s}) /(\mathrm{j}-\mathrm{i})
$$

Using the 2001 and 2011 census data separately for each sex by 5 -year age groups (under 1, 1-4, 5$9, \ldots, 80+$ ) as the base population, AGEINT was used to derive (interpolate) mid-year population by age and sex for each year for the period 2001-2009.

Table B4.1. Sample AGEINT for mid-year 2008 for Males
Linear Interpolation of Population by Age

| Item or Age | Earlier Population | Later Population | Interpolated Population |
| :--- | :---: | :---: | :---: |
| Type of Interpolation |  |  |  |
| (Enter ' 0 ' for linear or "1" for Exponential) | Linear |  |  |
| Year | 2001 | 2010 | 2008 |
| Month | 5 | 5 | 7 |
| Day | 22 | 10 | 1 |
|  | $22-M a y-01$ | $10-$ May-10 | $01-J u l-10$ |
|  |  |  |  |
| All ages | 76,683 | 82,224 | 81,077 |
|  |  |  | 1,257 |
| Under 1 | 1,345 | 1,234 | 5,502 |
| 1 to 4 | 6,000 | 5,372 | 7,373 |
| 5 to 9 | 8,684 | 7,031 | 7,576 |
| 10 to 14 | 8,156 | 7,425 | 8,085 |
| 15 to 19 | 8,182 | 8,060 | 6,670 |
| 20 to 24 | 6,636 | 6,679 | 6,412 |
| 25 to 29 | 6,145 | 6,482 | 6,032 |
| 30 to 34 | 5,780 | 6,098 | 5,804 |
| 35 to 39 | 5,484 | 5,888 | 5,639 |
| 40 to 44 | 4,397 | 5,964 | 5,019 |
| 45 to 49 | 3,447 | 5,429 | 4,056 |
| 50 to 54 | 2,745 | 4,398 | 2,949 |
| 55 to 59 | 2,205 | 3,143 | 2,491 |
| 60 to 64 | 1,864 | 2,655 | 1,983 |
| 65 to 69 | 1,701 | 2,057 | 1,634 |
| 70 to 74 | 1,348 | 1,708 | 1,123 |
| 75 to 79 | 1,074 | 1,135 | 1,472 |
| $80+$ | 1,488 | 1,467 |  |

The assumption of constancy in the average annual change in each age group means a more or less equal distribution of the components of change over the period. A distribution of the components as presented in appendix table B1.6 over the intercensal period would therefore be as shown in table B4.2.

Table B4.2. Components of population change from census 2001 to census 2010 distributed

| Item | Male | Female | Total |
| :--- | ---: | ---: | ---: |
| Components for intercensal period May 23, 2001-Census May 10, 2010 |  |  |  |
| Births | 13,093 | 12,423 | 25,516 |
| Deaths | 5,191 | 4,218 | 9,409 |
| Migration | $-2,361$ | $-4,888$ | 7,249 |
| Census 2001- mid-year 2001 |  |  |  |
| Births | 160 | 152 | 312 |
| Deaths | 63 | 51 | 115 |
| Migration | 29 | 60 | 89 |
| Population at mid-year 2001 | 76,751 | 80,090 | 156,841 |
| Mid-year 2001-mid-year 2009 |  |  |  |
| Births | 11,679 | 11,087 | 22,766 |
| Deaths | 4,632 | 3,768 | 8,400 |

| Item | Male | Female | Total |
| :--- | ---: | ---: | ---: |
| Components for intercensal period May 23, 2001-Census May 10, 2010 |  |  |  |
| Migration | 2104 | 4,360 | 6,464 |
| Population at mid-year 2009 | 81,694 | 83,049 | 164,743 |
| Mid-year 2009 - Census 2010 |  |  |  |
| Births | 1,251 | 1,188 | 2,439 |
| Deaths | 496 | 404 | 900 |
| Migration | 226 | 467 | 693 |
| Population at Census 2010 | 82,224 | 83,367 | 165,591 |

## Step 5 Deriving postcensal mid-year population estimates for 2010-2014

The postcensal period represents the years following the most recent census and in the case of Saint Lucia the years following 2010. The MOVEPOP spreadsheet from the PASEX group was adapted to producing postcensal estimates. MOVEPOP estimates the population growth rate for the census date and uses it to move the census population to another desired date. Then it proportionally distributes the estimated total population by age and sex based on the distribution of the census population. In the same way the spreadsheet derives the population growth rate from one year to the next and moves the initial population to the desired date. It then proportionally distributes the estimated total population by age and sex based on the distribution of the initial population.

## a. Required Inputs for MOVEPOP

1. Initial population by age and sex
2. Sex and age specific death rates for initial population data
3. Age specific birth rates for initial data
4. Annual net number of migrants

The age specific rates for deaths and births are calculated from the registration data by age and sex. To estimate migration in the period after the census the relationship between migration and natural increase between 2001 and 2010 is held constant. Migration represented $-45 \%$ of natural increase based on the intercensal estimation. For the postcensal estimates therefore, natural increase (the difference between births and deaths) is first calculated and the migration is taken to be $45 \%$ of that figure as a minus quantity reflective of a net outward movement.

For Saint Lucia, the postcensal estimates for the year are required before all the data for the vital events for that year become available. After 2010, the procedure therefore is to use one half of the previous year's events plus the half of the current year's events (the year for which estimates are required).

Postcensal estimates are subject to revision when a new census is conducted at which time the series beginning with 2010 will become intercensal estimates.

Table B5.1. Example of Inputs for mid-year postcensal estimates up to 2014

| Mid-year | Base year | Births | Deaths | Migration |
| :---: | :---: | :---: | :---: | :---: |
| 2010 | Census 2010 | Full year 2010 | Full year 2010 | Full year 2010 |
| 2011 | 2010 | one half of 2010 added to one half of 2011 | one half of 2010 added to one half of 2011 | one half of 2010 added to one half of 2011 |
| 2012 | 2011 | one half of 2011 added to one half of 2012 | one half of 2011 added to one half of 2012 | one half of 2011 added to one half of 2012 |
| 2013 | 2012 | one half of 2012 added to one half of 2013 | one half of 2012added to one half of 2013 | one half of 2012added to one half of 2013 |
| 2014 | 2013 | one half of 2013 added to one half of 2014 | one half of 2013 added to one half of 2014 | one half of 2013 added to one half of 2014 |

Table B5.2. Postcensal components of change: full year 2010-2014

| Year | Births | Deaths | Natural Increase | Migration* |
| :---: | :---: | :---: | :---: | :---: |
| 2010 | 2,321 | 1,021 | 1,300 | -585 |
| 2011 | 2,001 | 1,098 | 903 | -406 |
| 2012 | 2,006 | 1,184 | 822 | -370 |
| 2013 | 2,175 | 1,113 | 1,062 | -478 |
| 2014 | 2,026 | 1,358 | 668 | -301 |

*Calculated as $-45 \%$ of natural increase
Note: the figure for births in 2010 is the revised figure.
Table B5.3. Postcensal components of change: using half year of current year plus half year of previous year (after 2010)

| Year | Births | Deaths | Natural Increase | Migration* |
| :---: | :---: | :---: | :---: | :---: |
| 2010 | 2,321 | 1,021 | 1,300 | -585 |
| 2011 | 2,161 | 1,060 | 1,102 | -496 |
| 2012 | 2,004 | 1,141 | 863 | -388 |
| 2013 | 2,091 | 1,149 | 942 | -424 |
| 2014 | 2,101 | 1,236 | 865 | -389 |

[^1]
## b. Calculation mid 2010 Population

Inputs:

- Base population - census 2010
- Mortality - age specific rates 2010
- Fertility - age specific rates 2010
- Migration - 2010 total

Table B5.4. Summary of mortality and fertility inputs for mid-2010 population from MOVEPOP

| Age | Full year 2010 deaths |  | Age specific death rates |  | Age of Mother | Total <br> Births | Age Specific Fertility rates |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Male | Female | Male | Female |  |  |  |

| Total | 82,575 | 83,723 |

## Step 6 Estimating District Population

Once the national totals by age for the censuses were finalized the district totals were adjusted to conform to these totals.

## a. Calculating district intercensal estimates

First the census 2001 figures by age for each district arranged in a matrix separately for each sex were adjusted to conform to the adjusted national figures. An adjustment factor for each age group was derived (national total for age $\mathrm{x} /$ district total for age x ). The population at age x for each district was then multiplied by the factor to get new numbers which when added together give the total consistent with the national total. The process was repeated for the 2010 census. The intercensal estimates for each district were derived using the AGEINT spreadsheet in the same way as for the national intercensal estimates. A matrix showing the age distribution of the districts as derived from AGEINT was produced for each year. The district totals were then adjusted to fit the national totals for the
mid-year in the same way as the census figures were. The procedure was repeated for each year. The output for year 1 becomes the input for year 2. Mid 2001 is the base for mid-2002 and mid-2002 is the base for mid-2003 and so on until mid-year 2009.

## b. Calculating district postcensal estimates

For the postcensal district estimates the census 2010 distribution is held constant for each year. The census 2010 totals in the matrix are adjusted to the national totals for mid-2010 to derive the mid- 2010 by district. Then the mid-2010 distribution is adjusted to the national mid-2011 total and so on.

Table B6.1: Original census 2001 population by age and sex for districts with adjustment factors for national totals-MALES

| Age | Castries | Anse-LaRaye | Canaries | Soufriere | Choiseul | Laborie | Vieux Fort | Micoud | Dennery | Gros Islet | Total | National Total | Adjustment factor |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 506 | 52 | 18 | 90 | 46 | 54 | 137 | 142 | 151 | 147 | 1,343 | 1,345 | 1.002016 |

## SECTION 2

## POPULATION PROJECTIONS 2010-2030

## Global Population Dynamics

Assumptions of future growth are guided by past trends in changes of population and its components. Caribbean demographic development over the past thirty to forty years has followed a similar path to many developing countries. Fertility has declined quite markedly in the majority of developing countries and continues to decline everywhere as the fertility transition, the movement from high to low fertility is now almost universal. The average total fertility rate (the average number of children per woman) which was about 4.0 for developing countries in 1980-1990 was 2.8 by 2000-2010. For the Caribbean as a whole the movement over the same period was from 3.3 to 2.4 (United Nations, World Population Prospects 2017).

Notwithstanding the effect of the HIV/AIDS epidemic which left some countries reeling, average life expectancy at the global level rose from about 62 years to 69 years, an addition of 7 years in the thirty years between 1980 and 2010.

As international migration remains at the forefront of the international agenda, the United Nations (2017b) data show that at 2010 about $3 \%$ of the world's population, an estimated 220 million people, were international migrants. This represented an increase of nearly 50 million over the 173 million estimated at the year 2000. International migrants of Caribbean origin totalled about 1.4 million in 2010, an increase of $7.7 \%$ over the 1.3 million estimated for 2000.

One of the important demographic consequences of decreased levels of fertility and increased life expectancy is ageing of populations. Population ageing simply refers to increasing proportions of older persons within the population. As a population ages the proportion of older persons increases while the proportion of the youngest declines.

Table (i). Summary of Global Age Distribution, 1980 and 2010 (Population in thousands)

|  |  |  |  | Annual rate of growth <br> Item |
| :--- | ---: | ---: | ---: | ---: |
|  | 1980 | 2010 | Increase |  |
| World |  |  |  |  |
| Total | $4,458,412$ | $6,958,159$ | $2,499,747$ | 1.48 |

Source: United Nations. World Population Prospects the 2017 Revision. (See technical notes and data sources for details).

Tables (i) and (ii) present the age distribution of the global and regional population for 1980 and 2010. The global population aged 65 years and over numbered about 129 million in 1980. By 2010 the number had increased four-fold to 532 million. In percentage terms the rise was from about $2.9 \%$ to $7.6 \%$ of the total population. For the Caribbean countries as a whole, the population 65 years and over grew at an average annual rate of $2.4 \%$ between 1980 and 2010, twice the rate for the total population. The population of this age group numbered about 1.8 million in 1980 and by 2010 had doubled to reach 3.6 million, from $5.9 \%$ to $8.6 \%$ of the total population in the thirty years.

The pattern observed globally and for the Caribbean for the population under 15 years old, was one of numerical increases but decreased proportions. At the global level the population of this age group rose from 1.57 billion to 1.86 billion, an addition of 291 million persons between 1980 and 2010. In proportional terms however, this was a decline from $35.3 \%$ to $26.8 \%$ of the total population. For the Caribbean, the addition over the same period was 620,000 from 10.8 million to 11.0 million. This represented a fall in percentage terms by 9 percentage points from $36.5 \%$ to $27.5 \%$ of the total population. It should be noted that fertility declines do not translate directly in the growth of the young population because of increasing numbers in the female population of reproductive age, those 15-49 years old. Globally just over 734 million persons were added to this age group over the thirty years while for the Caribbean the number added was approximately 3.7 million, about $0.5 \%$ of the global increase.

The review of global demographic trends provides a context for the examination of demographic indicators for Saint Lucia. These indicators will provide a basis for the assumptions required for the population projections.

## Population Dynamics - Saint Lucia

Since 1980 the population of Saint Lucia has been growing but at a much reduced rate. Between 1980 and 2001 the population grew at an average $1.5 \%$ annually. Since 2001, the rate has been cut drastically to $0.6 \%$. This reduction is primarily due to falling fertility levels.

## Fertility

Table (iii) presents data for the most basic of fertility indicators, the number of births and the crude birth rate for the intercensal periods for Saint Lucia beginning with 1980. The table shows a consistent decline from just over 4,000 births between 1980 and 1991 to 2,800 between 2001 and 2010, a fall by almost $50 \%$ in the thirty years. The rates reflect the downward movement falling from 32.5 per 1,000 to 17.6 per 1,000 over the same period.

## Table (iii). Average Annual Number of Births and Crude Birth Rates, 1980-2010

| Census Period | Average Annual Births | Crude Birth Rate per 1000 |
| :--- | :---: | :---: |
| $1980-1991$ | 4,076 | 32.5 |
| $1991-2001$ | 3,378 | 23.1 |
| $2001-2010$ | 2,835 | 17.6 |

Source: Calculations from census reports (See technical notes and data sources for details).

One measure of fertility which may be examined is census data on children ever born to women of ages 15-49 years old at the time of the census. Table (iv) presents the data from the censuses of 1980, 2001 and 2010. The decreases over the thirty years are evident. In 1980, for every 1,000 women of ages 15-49 years there were on average 3,599 children. By 2001 this had fallen to 2,300 and by 2010 to an even lower 1,509 . As expected, children ever born increases with age. At 1980, the movement was from a low of 323 per 1,000 for the youngest to 6,224 for the oldest women. At 2010, the pattern was similar but the gap wider, rising from 73 per 1,000 for the youngest to 2,912 per 1,000 for the oldest.

With respect to changes over the thirty years, a fall in numbers is observed for all women. The largest decline was among the youngest. Children ever born per 1,000 women of ages $15-19$ years fell by $77 \%$ from 323 per 1,000 in 1980 to 198 per 1,000 in 2001 and to 73 per 1,000 in 2010. The next highest decreases appear for women of ages between 20 and 34 years old with a decline of $62 \%$ from an average of 2,589 per 1,000 in 1980 to 973 per 1,000 in 2010. The number of children ever born for the oldest women was cut by one half falling by $53 \%$ from 6,224 per 1000 to 2,912 per 1,000 between 1980 and 2010.

Table (iv). Children ever born per 1,000 women for females 15-49 years at censuses 1980, 2001 and 2010

|  | Children per 1000 Women |  |  | \% change 1980- |
| :--- | ---: | ---: | ---: | :---: |
| Age Group | 1980 | 2001 | 2010 | 2010 |
| $15-19$ | 323 | 198 | 73 | -77.4 |
| $20-24$ | 1,295 | 709 | 474 | -63.4 |
| $25-29$ | 2,556 | 1,381 | 928 | -63.7 |
| $30-34$ | 3,915 | 2,203 | 1,516 | -61.3 |
| $35-39$ | 5,060 | 2,798 | 2,069 | -59.1 |
| $40-44$ | 5,817 | 3,385 | 2,589 | -55.5 |
| $45-49$ | 6,224 | 3,539 | 2,912 | -53.2 |
| Average | $\mathbf{3 , 5 9 9}$ | $\mathbf{2 , 0 3 0}$ | $\mathbf{1 , 5 0 9}$ | $\mathbf{- 5 8 . 1}$ |

Source: Calculations from census reports ((See technical notes and data sources for details).

Current fertility which forms the basis for the projections is the subject of table (v). The table is derived from the statistics on births by age of mother for women 15-49 years old from vital statistics registration for 2001 and 2010 and from the census question on current fertility (births in past 12 months) for 1980.

Table (v). Saint Lucia: Age Specific Fertility Rates per 1,000 women 15-44 years old at 1980, 2001 and 2010

|  | Children per 1000 Women |  |  | \% change |
| :--- | ---: | ---: | ---: | :---: |
| Age Group | 1980 | 2001 | 2010 | 1980-2010 |
| $15-19$ | 141.4 | 83.3 | 51.2 | -63.9 |
| $20-24$ | 226.1 | 125.9 | 99.6 | -55.9 |
| $25-29$ | 190.7 | 121.2 | 78.0 | -59.1 |
| $30-34$ | 153.0 | 104.3 | 68.3 | -55.4 |
| $35-39$ | 117.2 | 60.1 | 40.4 | -65.5 |
| $40-44$ | 52.9 | 21.4 | 14.6 | -72.4 |
| Total Fertility Rate per woman | 4.4 | 2.6 | 1.8 | -59.1 |

Note: (I): Births for 6 women at ages 45-49 in 2001 and for 4 women in 2010 included with the 40-44 years women.
Source: Calculations from census reports (See technical notes and data sources for details).

The typical pattern is for rates to be lowest among the youngest and then increase with age. The table shows that for Saint Lucia, rates have been highest for women 20-24 years old at the three dates. For this age group, the age specific fertility rate per 1,000 women which stood at 226.1 at census 1980 moved down to 125.9 in 2001 and by 2010 was 99.6 , an overall decrease of about $56 \%$. The next highest rates observed which are for the $25-29$ years group declined by $59 \%$ from 190.7 per 1,000 in 1980 to 78.0 per 1,000 at 2010 . Rates which are lowest for the oldest have seen the greatest declines from 52.9 per 1,000 in 1980 to 14.6 per 1,000 in 2010 , an overall drop by approximately $72 \%$.

The total fertility rate (TFR) derived from prevailing age specific fertility rates represents the average number of children per woman. The TFR is a very important fertility indicator and is central to the concept of 'replacement level fertility.' Replacement level fertility is attained when the TFR is 2.1 . Table (v) shows that consistent with the decreases in age specific fertility rates, there have been declines in the TFR which by 2010 had fallen below replacement level. In 1980, the TFR was 4.4 and by 2010 had dropped to 1.8 , a cut of $59 \%$.

## Mortality

Table (vi). Saint Lucia: Average Annual Number of Deaths and Crude Deaths Rates, 1960-2010

| Census Period | Average Annual Deaths | Crude Death Rate per 1000 |
| :--- | :---: | :---: |
| $1980-1991$ | 876 | 7.0 |
| $1991-2001$ | 945 | 6.5 |
| $2001-2010$ | 1,045 | 6.5 |

Source: Calculations from census reports (See technical notes and data sources for details).

Average deaths for the population and the crude death rates for the thirty year period from 1980 are shown in table (v). Average deaths have been around 900 to 1,000 , while death rates have been around 7 per 1000 .

Life expectancy is a key indicator of the mortality experience of a population and is a basic input for population projections. The estimates are calculated separately for men and women.

Establishing a reasonable historical series of life expectancies for Saint Lucia since 1980 has been challenging. A series beginning with 1890-92 and continuing up to 1979-81 was presented in the analytic report for the 1980 census published by the CARICOM Secretariat (see references). Since that time, Statistics Saint Lucia has published life expectancies for 1994, 1995, 2002 and 2003. These are presented in table (vii). The
pattern appears inconsistent with the most glaring inconsistency being the drop of 3 years for men in the one year between 1994 and 1995 followed by a gain of almost 5 years by 2002. These estimates are therefore not considered reliable.

Table (vii). Estimated Life Expectancies at Birth for Males and Females, 1994, 1995, 2002, 2003

|  | Expectation of Life at Birth (Years) |  |
| :---: | :---: | :---: |
| Year | Male | Female |
| 1994 | 69.69 | 74.81 |
| 1995 | 66.41 | 74.94 |
| 2002 | 71.96 | 76.73 |
| 2003 | 71.34 | 76.16 |

Source: Saint Lucia Vital Statistics Report, 1995 and 2014. (See technical notes and data sources for details).

One useful source of data on life expectancy is the World Health Organization (WHO), Global Health Observatory (GHO) data repository. This repository is the WHO's gateway to health-related statistics for its 194 Member States. The series of life tables maintained for Saint Lucia begins at the year 2000. For the projections, an estimate around 2010 is needed. Using the methodology described in the technical notes which appear as an appendix to this report, estimates for 2010 were derived consistent with the 2000. For Saint Lucia, the estimated life expectancy for men at 2010 is 71.4 years and for women 77.9 years. Table (viii) shows that the gains in years since 1980, are about 6 years for men, compared to the approximately 8 years for women, an overall gap of 2 years.

Table (viii). Saint Lucia: Life Expectancy for Males and Females, 1980-2010

| Year | Expectation of Life at Birth (Years) |  |  |
| :--- | :---: | :---: | :---: |
|  | Male | Female | Male/Female Gap |
| 1980 | 65.65 | 69.98 | 4.33 |
| 2000 | 70.19 | 74.13 | 3.94 |
| 2010 | 71.44 | 77.87 | 6.43 |
| Total Gains in Years 1980-2010 | 5.79 | $\mathbf{7 . 8 9}$ | $\mathbf{2 . 1 0}$ |
| Annual Average Gains in Years | 0.19 | 0.26 | 0.07 |
| 1980-2010 |  |  |  |
| Total Gains in Years 2001--2010 | 1.25 | 3.74 | 2.50 |
| Annual Average Gains in Years | 0.14 | 0.42 | 0.28 |
| 2001-2010 |  |  |  |

Source: Roberts (1980) and World Health Organization. (See technical notes and data sources for details).

## Migration

Of the three components of national population change, migration is the most difficult to measure. Whereas the processes of fertility and mortality move rather slowly, migration is associated with large and sudden changes, making it, very often, unpredictable and difficult to study. Following United Nations recommendations, a number of methods are employed internationally to measure migration. Saint Lucia does not maintain migration records in any form. For many countries, migration is estimated to be the residual after births and deaths in an intercensal
period are accounted for. Table (ix) presents the accounting for migration as a component of population change for Saint Lucia for the period 1980-2010.

Table (ix). Estimates of migration for census years, 1980-2010

| Census Year | Population | Intercensal Change | Natural Increase | Implied Migration |
| :--- | :---: | :---: | :---: | :---: |
| 1980 | 115,252 |  |  |  |
| 1991 | 135,791 | 20,539 | 35,200 | $-14,661$ |
| 2001 | 156733 | 20,942 | 24,334 | $-3,392$ |
| 2010 | 165,591 | 8,858 | 16,107 | $-7,249$ |

Source: Calculations from census reports (See technical notes and data sources for details).

There is no apparent explanation for the large fall off in migration from the $-14,661$ between 1980 and 1991 to $-3,392$ in the subsequent period. This would require a detailed analysis of the changes over the period, which is outside the scope of this report.

Going forward in the postcensal period and for projections, assumptions based on the intercensal pattern can be made. Using this approach, the estimates of migration for the most recent intercensal period has been derived and presented in table (x). Based on this approach annual migration for Saint Lucia for the period is estimated at about -800.

Table (x). Saint Lucia: Components of Population Change and Estimated Migration, 2001-2010

| Item | Total |
| :--- | ---: |
| Census 2001 Population | 156,733 |
| Census 2010 Population | 165,591 |
| Total Population Increase | 8,858 |
| Births 2001-2010 | 25,516 |
| Deaths 2001-2010 | 9,409 |
| Natural Increase 2001-2010 | 16,147 |
| Assumed Total Migration 2001-2010 | $-7,249$ |
| Annual Migration | 809 |
| Migration as a \% of Natural Increase | $-45 \%$ |

Source: See Section 1 procedures for estimating intercensal population

A useful source of information for countries is the census reports on the foreign born of other countries, in most cases the dominant receiving countries. An especially useful source is the United Nations Trends in International Migrant Stock Report and database. The 2017 revision of this report covers the period 1990-2017. The main source of this data are the national censuses. Based on the tables which present migrants by country of origin and country of destination, the data for Saint Lucia appear in table (xi).

Table (xi). Saint Lucia Migrant Stock: at mid-year, 1990-2017

| Year | Migrants to Saint Lucia |  |  | Migrants from Saint Lucia |  |  |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
|  | Male | Female | Total | Male | Female | Total |
| 1990 | 2,616 | 2,689 | 5,305 | 10,053 | 11,953 | 22,006 |
| 1995 | 3,560 | 3,592 | 7,152 | 13,837 | 16,870 | 30,707 |
| 2000 | 4,950 | 4,918 | 9,868 | 17,696 | 21,920 | 39,616 |
| 2010 | 5,783 | 5,685 | 11,468 | 20,531 | 26,450 | 46,981 |
| 2015 | 6,106 | 5,994 | 12,100 | 21,533 | 29,101 | 50,634 |
| 2017 | 6,446 | 6,325 | 12,771 | 22,375 | 30,989 | 53,364 |
| Change 1990-2010 | 3,167 | 2,996 | 6,163 | 10,478 | 14,497 | 24,975 |
| Change 2010-2015 | 323 | 309 | 632 | 1,002 | 2,651 | 3,653 |

Source: United Nations Trends in International Migrant Stock, the 2017 Revision. (See technical notes and data sources for details).

The figures show an overall increase of about 6,200 immigrants to Saint Lucia between 1990 and 2010 while the increase for emigrants over the same period was about 25,000 showing a net of about $-18,800$ over the 20 -year period; an annual outflow of 940 . The changes seen for the period 2010-2015 reflect a declining number of annual migrants. The total outflow over the 5 years was 3.653 compared to the total inflow of 632 . The result is a net outflow of 3,021 over 5 years, approximately 600 annually.

Table (xii). Saint Lucia: Sex distribution of Migrants from Saint Lucia, 1990-2017

|  | \% of Total |  |
| :--- | :---: | :---: |
| Year | Male | Female |
| 1990 | 45.7 | 54.3 |
| 1995 | 45.1 | 54.9 |
| 2000 | 44.7 | 55.3 |
| 2010 | 43.7 | 56.3 |

Source: United Nations Trends in International Migrant Stock, the 2017 Revision. (See technical notes and data sources for details).

Migrants are predominantly women and table (xi) shows an increasing percentage of women over the period covered by the UN data, from approximately $54 \%$ at 1990 up by 4 percentage points to about $58 \%$ by 2017 .

Despite limitations, the UN database provides a useful source for an age distribution of migrants, there being no other source. The limitation is that the table on age of migrants is by country of destination only. So for example it is only possible to capture the age distribution of the migrants to Saint Lucia. While the destination for the majority of emigrants from Saint Lucia, more than one third (39\%), is the United States of America the Saint Lucian migrants represent a miniscule $.04 \%$ of migrants to that country. Using the age distribution of the migrant population to the USA as a proxy is therefore not considered meaningful. The age distribution considered more meaningful is based on the distribution for 15 Caribbean Countries among which there is quite a considerable inter regional movement. At 2010, the migrant population of these countries originating from within the group was 136,251 . Of these, 11,423 or $8 \%$ originated in Saint Lucia.

The age distribution of the migrants from Saint Lucia to the 15 selected Caribbean countries around 2010 appears in table (xiii).

Table (xiii). Age distribution (\%) of migrants from Saint Lucia to fifteen selected Caribbean Countries 2010

| Age Group | Male | Female |
| :--- | :---: | :---: |
| $0-4$ | 4.3 | 3.7 |
| $5-9$ | 5.2 | 4.6 |
| $10-14$ | 6.0 | 5.5 |
| $15-19$ | 6.8 | 6.3 |
| $20-24$ | 7.0 | 7.2 |
| $25-29$ | 8.2 | 8.7 |
| $30-34$ | 9.2 | 9.7 |
| $35-39$ | 9.3 | 9.9 |
| $40-44$ | 8.9 | 9.2 |
| $45-49$ | 8.0 | 8.4 |
| $50-54$ | 6.8 | 7.0 |
| $55-59$ | 5.8 | 5.9 |
| $60-64$ | 4.9 | 4.5 |
| $65-69$ | 3.7 | 3.5 |
| $70-74$ | 2.8 | 2.6 |
| $75-79$ | 1.4 | 1.3 |
| $80+$ | 1.7 | 2.0 |
| Total | 100.0 | 100.0 |

Countries: Antigua and Barbuda, Bahamas, Barbados, British Virgin Islands, Cayman Islands, Dominica, Grenada, Guadeloupe, Jamaica, Martinique, Saint Kitts Nevis, Saint Vincent and the Grenadines, Sint Maarten, Trinidad and Tobago, United States Virgin Islands.

Note: The age group 75 years and over provided in the database was separated using the proportional distribution for the 7579 years and the 80+ years from the census.

## Summary

The pattern of movement in the demographic indicators and in particular the decreased levels of fertility, increasing life expectancy and ageing of the population, provide the context for the assumptions regarding the future pattern of population movements for Saint Lucia.

## METHODOLOGY AND ASSUMPTIONS FOR THE PROJECTIONS

There are two main categories of projection methodologies. Component methods involve procedures for projecting the population considering the components of growth: fertility, mortality and migration. Projections are typically done for age and sex but variables such as race and citizenship are sometimes included. The ratio methods uses mathematical functions applied to population figures but not to each of the components.

The population projections for the resident population of Saint Lucia are produced by means of the Cohort Component Method. As explained previously, the component technique is based on assumptions about the components of demographic change-births, deaths and international migration-to project population growth. The overall basis for this method is what is referred to as the 'balancing equation' $\mathrm{P} 2=\mathrm{P} 1+(\mathrm{B}-\mathrm{D})+(\mathrm{I}-\mathrm{E})$ where $\mathrm{P} 1=$ population at earlier date, $\mathrm{P} 2=$ population at later date, $\mathrm{B}=\mathrm{Births}, \mathrm{D}=$ Deaths, $\mathrm{I}=$ Immigration and $\mathrm{E}=$ Emigration. A cohort is defined as a group of people who experience the same demographic event during a particular period of time, such as their year of marriage, birth, or death (Siegel and Swanson 2004, 755). The basis of the Cohort Component Method is age cohorts. Age cohorts are typically split between males and females. Dividing the population into age cohorts allows for the analysis of the differences in fertility, mortality and migration rates among different age groups and to consider how these rates change over time.

In keeping with current standard procedures for producing population projections, alternative assumptions related to the future movements of the three components of fertility, mortality and migration are developed. The assumptions for the components of change are based on time series analysis of historical trends.

The actual calculations have been developed using the MORTPAK for Windows software. MORTPAK is the United Nations package for demographic measurement in developing countries. The procedure used for these projections is contained in the MORTPAK application PROJCT which uses the cohort-component method and carries out single-year projection of a population by age and sex, based on initial male and female populations in five-year age groups and assumed levels and changes in fertility, mortality and migration.

The steps as described in the MORTPAK manual (United Nations 2003, 53) are as follows:

- Estimation of projected levels and age patterns of mortality, fertility and migration for each singleyear projection period;
- Estimation of the male and female populations by single years of age from the data in five-year age groups given as input;
- Sequential application of these annual age-specific mortality and fertility rates and migration to the population to provide annual projected populations by age and sex and demographic indicators.

The programme requires a specific format for the input data which represents the assumptions. Following is a description of the input data and the assumptions related to fertility, mortality and international migration. Details of the calculations are presented as an Appendix.

The PROJCT application requires the following inputs related to the three components of change, fertility, mortality and migration:

- A base population by five year age groups $0 . . .80+$ separately for males and females;
- Age specific fertility rates per woman (15-44 years or 15-49 years) at the initial (base) period and at the end period;
- Age specific mortality rates separately for males and females for one period;
- Number of migrants by age and sex for one period; and
- Assumed indicators (life expectancy, total fertility rate, number of migrants) for the base period, the years in between and the end period.

## THE BASE POPULATION

The base population is the population at mid-2010 previously derived and presented in Section 1 of this report. For the projections, this population is smoothed using the AGESMTH spreadsheet from the PASEX group. Smoothing is recommended to get rid of irregularities in the age data.

Table (xiv). Base year 2010 population for projections

|  | Original Mid-year |  |  | Smoothed Mid-year |  |  |
| :---: | ---: | :---: | ---: | :---: | ---: | ---: |
| Age Group | Male | Female | Total | Male | Female | Total |
| $0-4$ | 6,610 | 6,320 | 12,930 | 6,610 | 6,320 | 12,930 |
| $5-9$ | 7,035 | 6,750 | 13,785 | 7,035 | 6,750 | 13,785 |
| $10-14$ | 7,430 | 7,308 | 14,738 | 7,781 | 7,460 | 15,241 |
| $15-19$ | 8,064 | 7,662 | 15,726 | 7,713 | 7,510 | 15,223 |
| $20-24$ | 6,683 | 6,780 | 13,463 | 6,795 | 6,881 | 13,677 |
| $25-29$ | 6,486 | 6,647 | 13,133 | 6,374 | 6,546 | 12,919 |
| $30-34$ | 6,101 | 6,011 | 12,112 | 6,105 | 6,247 | 12,351 |
| $35-39$ | 5,892 | 6,245 | 12,137 | 5,888 | 6,009 | 11,898 |
| $40-44$ | 5,967 | 6,105 | 12,072 | 6,030 | 6,085 | 12,115 |
| $45-49$ | 5,433 | 5,396 | 10,829 | 5,370 | 5,416 | 10,786 |
| $50-54$ | 4,400 | 4,420 | 8,820 | 4,187 | 4,242 | 8,429 |
| $55-59$ | 3,145 | 3,270 | 6,415 | 3,358 | 3,448 | 6,806 |
| $60-64$ | 2,656 | 2,757 | 5,413 | 2,643 | 2,780 | 5,423 |
| $65-69$ | 2,058 | 2,265 | 4,323 | 2,071 | 2,242 | 4,313 |
| $70-74$ | 1,709 | 1,841 | 3,550 | 1,709 | 1,841 | 3,550 |
| $75-79$ | 1,137 | 1,409 | 2,546 | 1,137 | 1,409 | 2,546 |
| $80+$ | 1,468 | 2,231 | 3,699 | 1,468 | 2,231 | 3,699 |
| Total | 82,274 | 83,417 | 165,691 | 82,274 | 83,417 | 165,691 |

## FERTILITY

Age specific fertility rates and the total fertility rate (TFR) per woman are calculated for 2001 and 2010 using births by age of mother related to the original census population of females. The data show a decline in the TFR from 2.57 to 1.76. The initial age specific rates for each projection scenario will be the rates for 2010.

## Fertility Assumptions

There is a basic assumption that the conditions which have facilitated the fall in fertility levels will persist in the future. As the projections for Saint Lucia begin with fertility at a level below replacement level, the issue is how low fertility levels can get. The 2015 World Fertility Report of the United Nations states that "contrary to the global trend of declining fertility, several below-replacement fertility countries (32) experienced fertility increases over the past 15 years." The view is expressed however that "despite these trend reversals, no country with belowreplacement level fertility has yet returned to replacement-level fertility." (UN 2017, xiii). The assumptions going forward were developed based on the approach recommended by the Demographic Observatory of ECLAC (2011)
which explains that the TFR projection is based on two assumptions. The first assumption is that the TFR will evolve according to a logistic behaviour pattern in which it declines gradually. The second assumption is that upon reaching a TFR of $1.5,1.6$ or 1.7 children per woman, the downward trend will reverse and the TFR will recover but will not exceed the replacement level of 2.1 children per woman. The calculation for the logistic pattern was done using the TFRGLST spreadsheet from the PASEX series developed by the United States Census Bureau. Using the base of a TFR of 1.76 at July 1, 2010 the extrapolation for future levels for the medium projections produces a continuous decline to 1.56 at 2025-2026. Beginning in 2026-2027 there is an upturn to 1.57 and to 1.59 by 2030.

For the low variant, the fertility is assumed to remain below the medium scenario by 0.125 births per woman in the first projection period and 0.25 births per woman thereafter. For the high variant, the TFR is assumed to be higher than the medium by 0.125 births per woman in the first projection period and by 0.25 births per woman thereafter.

Age specific fertility rates consistent with the assumed levels of the TFR are produced using the ASFRPATT from the PASEX series.

Table (xv). Total fertility rate assumptions for alternate projections, 2010-2030

|  | Base | Average |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Alternate Projections | 2010 | $2010-2015$ | $2015-2020$ | $2020-2025$ | $2025-2030$ |
| Low | 1.76 | 1.60 | 1.41 | 1.32 | 1.33 |
| Medium | 1.76 | 1.70 | 1.61 | 1.57 | 1.58 |
| High | 1.76 | 1.80 | 1.81 | 1.82 | 1.83 |

Table (xvi). Age specific fertility rate assumptions for alternate projections, 2010-2030

|  |  | Alternate Projections: 2030 |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Age Group | Base Year 2010 | Low | Medium | High |
| $15-19$ | 0.05122 | 0.01988 | 0.02521 | 0.03055 |
| $20-24$ | 0.09959 | 0.06937 | 0.08678 | 0.10419 |
| $25-29$ | 0.07796 | 0.11205 | 0.12406 | 0.13608 |
| $30-34$ | 0.06831 | 0.04818 | 0.05811 | 0.06804 |
| $35-39$ | 0.04045 | 0.01469 | 0.01875 | 0.02282 |
| $40-44$ | 0.01385 | 0.00341 | 0.00448 | 0.00554 |

## MORTALITY

Age specific death rates are based on the average deaths for 2001-2010 related to the original adjusted census population. A life table and smooth age specific values are generated using the LTPOPDTH spreadsheet in the PASEX series. The life table shows a life expectancy for men of 71.4 years and for women 77.9 years.

## Mortality Assumptions

Using 71.4 years and 77.9 years as the base for the 3 scenarios, the low increases by 0.5 years in each five-year period to end at 73.4 years (men) and 79.9 years (women) in 2030. The medium increases by 1 year every five
years to reach 75.4 years (men) and 81.9 years (women) in the final period, and the high projection adds 1.5 years every five years and ends at 77.4 years for men and 83.9 years for women.

The major consideration for assumptions about the future course of mortality is how high life expectancy can go. Changes in life expectancy are generally explained within the context of the epidemiological transition. In summary, the theory proposes that the early growth in life expectancy resulted from the control over infectious diseases that often affect children. As the causes of mortality shift to non-communicable diseases and those of the more chronic and degenerative types more typical at the older ages, the greater challenges in controlling these types of diseases results in a slowing of the increase in life expectancy. Generally the higher the life expectancy the lower the level of gains expected.

Table (xvii). Life Expectancy Assumptions for Alternate Projections, 2010-2030

|  | Alternate Projections |  |  |
| :--- | :---: | :---: | :---: |
| Sex and Year | Low | Medium | High |
| Males |  |  |  |
| 2010 | 71.4 | 71.4 | 71.4 |
| 2015 | 71.9 | 72.4 | 72.9 |
| 2020 | 72.4 | 73.4 | 74.4 |
| 2025 | 72.9 | 74.4 | 75.9 |
| 2030 | 73.4 | 75.4 | 77.4 |
| Female |  |  |  |
| 2010 | 77.9 | 77.9 | 77.9 |
| 2015 | 78.4 | 78.9 | 79.4 |
| 2020 | 78.9 | 79.9 | 80.9 |
| 2025 | 79.4 | 80.9 | 82.4 |
| 2030 | 79.9 | 81.9 | 83.9 |

The assumption of a 1 year increase in life expectancy over 5 years as proposed by the medium scenario for the current projections is guided by the recent pattern of increase. Table (vi) shows that in the 9 years between the last two censuses there were gains of 1.25 years for men and 3.74 years for women respectively. The combined average annual gain was .28 years, just over 1 year for a five year period.

Table (xviii). Age specific death rates for population projections, 2010-2030

| Age Group | Male | Female |
| :---: | ---: | :--- |
| 0 | 0.0177883 | 0.018174 |
| $1-4$ | 0.002661 | 0.002383 |
| $5-9$ | 0.003806 | 0.001753 |
| $10-14$ | 0.002856 | 0.002081 |
| $15-19$ | 0.005644 | 0.002928 |
| $20-24$ | 0.010528 | 0.003098 |

## MIGRATION

The United Nations $(2017,29)$ states:
International migration is the component of population change [which is] the most difficult to project. This is primarily due to the fact that data on past trends are often sparse or incomplete, and because the movement of people across international borders, is a very volatile process. Not only has international migration shown drastic changes in absolute numbers, but the direction of the flows has changed as well. As a result, some countries that historically have been primarily countries of origin have become countries of destination and vice versa. Therefore, formulating assumptions about future trends in international migration is extremely challenging.

## Migration Assumptions

Migration assumptions for population projections are expressed in terms of net numbers of international migrants, representing the difference between the number of immigrants and the number of emigrants over a period of time. The assumptions for the projections have been developed on the basis of the pattern observed from the data examined previously. This pattern is for a net outflow which is expected to continue but at a reduced level.

The challenges faced in the estimation of migration for Saint Lucia has been discussed. The assumptions for the projections have been developed from the considerations indicated using the intercensal estimates and the United Nations database.

The annual net migration of -800 is assumed for all projections at the base period. Declines are assumed over the period for all projections. For the low scenario migration will increase by 200 every five-year period up to 2020 at which point it will be $-1,200$. The decreases after that is by -200 for each five-year period ending at 800 by 2030. The medium scenario will see the initial -800 declining to -700 and by 2025 to -550 before falling to 450 by the end of the projection period. For the high scenario, there is a $50 \%$ reduction to -400 in the first five years after which the levels fall to 200 and then to 100 by 2030.

Table (xix). Saint Lucia: Net Annual Migrants Assumed for Population Projections, 2010-2030

| Sex | 2010 | 2015 |  | 2020 | 2025 | 2030 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  | Low |
| Male | -360 | -450 | -540 | -450 | -360 |  |
| Female | -440 | -550 | -660 | -550 | -440 |  |
|  |  | Medium |  |  |  |  |
| Male | -360 | -315 | -315 | -247 | -202 |  |
| Female | -440 | -385 |  | -385 | -303 | -248 |
|  |  | High |  |  |  |  |
| Male | -360 | -180 | -90 | -45 | -45 |  |
| Female | -440 | -220 | -110 | -55 | -55 |  |

## THE PROJECTION RESULTS

## POPULATION SIZE AND GROWTH

The pattern of population movements for Saint Lucia over the projection period is expected to vary based on the scenario assumed (table (xx)) and figure 1. The population will increase continuously for both the medium and high variants based on assumptions of moderate and high fertility occurring simultaneously with moderate to high increases in life expectancy and small to moderate levels of migration. Under the medium scenario, the total population at 2030 is estimated to be 172,241 , reflecting an increase of 6,550 over the 2010 base of 165,691 . The movement under the high scenario is for an increase that is about 3 times the increase for the medium. By 2030 the population is estimated to be 185,657 , which is almost 20,000 higher than at 2010 . Under the low fertility scenario with small increases in life expectancy and a large volume of migration, there is a small increase of just fewer than 500 in the first period. This is followed by a continuous decline which increases for each projection period. For the low projection the population is expected to dip to 159,860 , a fall of approximately 5,800 over 2010.

Table (xx). Population Projections by Growth Scenarios, 2010-2030

|  | Low Projection |  | Medium Projection |  | High Projection |  |
| :--- | :---: | :---: | :---: | :---: | :---: | ---: |
| Year | Total | Change | Total | Change | Total | Change |
| 2010 | 165,691 |  | 165,691 |  | 165,691 |  |
| 2015 | 166,176 | 485 | 167,445 | 1,754 | 168,788 | 3,097 |
| 2020 | 164,591 | $-1,585$ | 169,155 | 1,710 | 173,958 | 5,170 |
| 2025 | 162,040 | $-2,551$ | 170,747 | 1,592 | 179,960 | 6,002 |
| 2030 | 159,860 | $-2,180$ | 172,241 | 1,494 | 185,657 | 5,697 |
| $2010-2030$ |  | $-5,831$ |  |  | 6,550 |  |

The population movements discussed are reflected in the annual growth rates as shown in table (xxi). In cases of population increases, average annual growth rates will remain low. The highest rate of increase observed for any five-year period is $0.68 \%$ for $2020-2025$ for the high projections. Under the medium scenario growth rates are expected to remain at $0.2 \%$ over the entire period. Under the low growth scenario, the population is projected to show annual rates of decline from about $0.2 \%$ beginning in 2015 and thereafter at approximately $0.3 \%$.

Figure 3. Population at Censuses 1980-2010 and Projections 2015-2030

## COMPONENTS OF GROWTH

The pattern of changes in the growth components of fertility, mortality and migration is shown in table (xxi) and illustrated in figures 4 to 6 .

## Fertility

Depressed rates of growth which are expected will result from the declining fertility. The annual number of births is expected to decrease consistently over the projection period for the low and medium scenarios only. According to the low projections, annual births fall by approximately $23 \%$, from 2,142 for 2010-2015, to 1,660 by 2030. The drop for the medium projections is by a smaller $10 \%$ from 2,280 at the initial period to 2,047 at the end of the period. For the high projections, births will increase but slowly over the period. Under this scenario the average annual number of births is expected to move from 2,417 in 2010 increasing to 2,522 for 2020-2025 after which the number will drop to the 2030 estimate of 2,438 . Crude birth rates will decrease in all projection scenarios. The largest drop is observed for the low fertility scenario with the low projection showing a crude birth rate of 10.4 per 1,000 at 2030 , down from 12.9 per 1,000 at the beginning of the projection period. With moderate or high fertility assumptions, as in the case of the medium and high projections, the crude birth rate moves down from approximately 14 per 1,000 initially and by 2030 is about $12-13$ per 1000 .

Table (xxi) Saint Lucia: Components of Growth and Main Demographic Indicators for Projection Period, 2010-2030

| Item | 2010-2015 | 2015-2020 | 2020-2025 | 2025-2030 |
| :---: | :---: | :---: | :---: | :---: |
| Low Projection |  |  |  |  |
| Absolute Numbers |  |  |  |  |
| Annual Births | 2,142 | 1,918 | 1,774 | 1,660 |

Figure 4. Components of Growth for Censuses 1980-2010 and Projections for 2015-2030 - Low Scenario

## Mortality

While the crude birth rate is projected to fall, there is expected to be a small but steady increase in the numbers of deaths. Average annual deaths will remain between 1,100 and 1,300 . For the medium variant which assumes moderate increases in life expectancy, the average number of deaths per year will be 1,169 at the initial period rising to 1,248 at the end. Comparative numbers for the low and high projections are 1,179 and 1,157 respectively in the 2010-15 period and 1,310 and 1,198 by 2025-2030. Death rates associated with these changes remain at an average of 7.0 per 1,000 over the period for the medium and high projections. The highest death rate observed over the period is 8.2 per 1,000 projected for the final five years of the low projection.

## Migration

According to the United Nations (2017):
Not only has international migration shown drastic changes in absolute numbers, but the direction of the flows has changed as well. As a result, some countries that historically have been primarily countries of origin have become countries of destination and vice versa. Therefore formulating assumptions about future trends in international migration is extremely challenging."

The assumptions for the population projections for Saint Lucia have been developed on the basis of the pattern observed from the data examined. This pattern is for a net outflow which is expected to continue but at reduced levels.

Projections for 2015-2030 - Medium Scenario

Figure 6. Components of Growth for Censuses 1980-2010 and Projections for 2015-2030 - High Scenario
$\rightarrow$ Births $\neg$-Deaths $\rightleftharpoons$ Migration

## SEX COMPOSITION

Women will continue to outnumber men under all three projection scenarios and the sex ratio (males per 100 females) will remain on average about 99 (table xxii). The deficit of males of approximately 1,100 at the beginning of the projection period is reduced by the end of the projection period under the medium variant by more than one-quarter, down to about 800 . The reduction for the low projection is estimated to be considerably higher, by about $65 \%$ down to approximately 400 . Under the high scenarios the deficit of males at 2030 is expected to be about 1,400 , an increase of $21 \%$ higher than at the beginning.

Table (xxii). Deficit of Males and Sex Ratio by Growth Scenarios, 2010-2030

| Projection Scenario and Year | Deficit of Males | Sex Ratio |
| :--- | :---: | :---: |
| Low Projection |  |  |
| 2010 | $-1,143$ | 98.6 |
| 2015 | -960 | 98.9 |
| 2020 | -711 | 99.1 |
| 2025 | -478 | 99.4 |
| 2030 | -398 | 99.5 |
| Medium Projection |  |  |
| 2010 | $-1,143$ | 98.6 |
| 2015 | -997 | 98.8 |
| 2020 | -891 | 99.0 |
| 2025 | -821 | 99.0 |
| 2030 | -835 | 99.0 |
| High Projection |  |  |
| 2010 | $-1,143$ | 98.6 |
| 2015 | $-1,022$ | 98.8 |
| 2020 | $-1,064$ | 98.8 |
| 2025 | $-1,196$ | 98.7 |
| 2030 | $-1,383$ | 98.5 |

## AGE STRUCTURE

The previous discussion on age structure used the age-sex pyramid as an effective way of highlighting changes over time. This analysis also uses age-sex pyramids to demonstrate the changing age structure of the population of Saint Lucia over the projection period. Figures 5-7 are pyramids with the age composition at the end of the projection period superimposed over the structure for the 2010 base year for the three growth scenarios. What is clearly evident in all three cases is the marked narrowing of the base and the widening of the top reflecting the declining fertility and the increasing proportions of older people in the population.

Figure 7. Age-Sex Pyramid at 2010 (shaded) and Low Projection

Figure 8. Age-Sex Pyramid at 2010 (shaded) and Medium Projection

Figure 9. Age-Sex Pyramid at 2010 (shaded) and High Projection

Table (xxiii). Distribution of the Population by broad Age Groups and Projection Scenarios, 2010-2030

| Projection Scenario and Age Group | 2010 |  | 2030 |  | 2010-2030 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number | \% of Total | Number | \% of Total | Absolute Change | Annual rate of growth (\%) |
| Low Projection |  |  |  |  |  |  |
| 0-14 years | 41,956 | 25.32 | 25,194 | 15.89 | -16,762 | -2.55 |
| 15-64 years | 109,627 | 66.16 | 111,371 | 70.22 | 1,744 | 0.08 |
| 65+ years | 14,108 | 8.51 | 22,035 | 13.89 | 7,927 | 2.23 |
| Medium Projection |  |  |  |  |  |  |
| 0-14 years | 41,956 | 25.32 | 30,871 | 17.92 | -11,085 | -1.53 |
| 15-64 years | 109,627 | 66.16 | 117,687 | 68.33 | 8,060 | 0.47 |
| 65+ years | 14,108 | 8.51 | 23,682 | 13.75 | 9,574 | 2.59 |
| High Projection |  |  |  |  |  |  |
| 0-14 years | 41,956 | 25.32 | 36,476 | 19.65 | -5,480 | -0.79 |
| 15-64 years | 109,627 | 66.16 | 123,874 | 66.72 | 14,247 | 0.58 |
| 65+ years | 14,108 | 8.51 | 25,306 | 13.63 | 11,198 | 2.92 |

The previous discussion on demographic dependency ratios focused on three main age groups, the 0-14 years, 15-64 years and 65 years and over. The youngest and the oldest are regarded as 'dependents' of the persons of working ages (15-64 years). Table (xxiii) and figures 10 to 12 present the population of these groups at the beginning and at the end of the projection period for the low, medium and high growth variants. The overall pattern is one of a decline among the youngest occurring simultaneously with rising numbers and proportions among the oldest.

At 2010, the population 0-14 years old numbered approximately 42,000 representing approximately onequarter of the total population. Under all three growth scenarios the population of this age group declines considerably. The reductions are to about 25,200 for the low growth, 30,900 for the medium growth and 36,500 for the high growth scenario. The annual rate of decline of $-2.6 \%$ for the low projection is the fastest. The slowest rate of decline for this age group over the period, $-0.7 \%$, is expected for the high projections while the rate for the medium projections is $-1.5 \%$. In proportional terms, the fall is projected to be from $25 \%$ at 2010 to approximately $16 \%, 18 \%$ and $20 \%$ respectively for the low, medium and high projections.

Figure 10. Population 0-14 years old at 2010 and for Projection Scenarios 2015-2030

The population of ages 15-64 years moves relatively minimally over the projection period with low rates of growth. The population accounted for just under two-thirds ( $66 \%$ ) of the total at 2010, and under the three growth scenarios adds between 2 and 4 percentage points to be between $68 \%$ and $70 \%$ of the total population. Under the low projections, the rate of growth is $0.08 \%$ with an addition of approximately 1,700 . The medium projections yields a rate of growth of $0.5 \%$ and adds approximately 8,100 while the high projections which sees a growth rate of $0.6 \%$ yields the largest addition, approximately 14,200 .

Figure 11. Population 15-64 years old at 2010 and for Projection Scenarios 2015-2030

By far the highest rates of growth observed from table (xxiii) are for the 65 years and over age group. In 2010 at the beginning of the projection period, the population in this age group numbered about 14,000 and accounted for about $9 \%$ of the total population. Under all three projection scenarios the population of 65 years and over is projected to grow at rates far in excess of rates seen for the total population. As a matter of fact as previously discussed, the population will decline for the low variant and will grow at rates of less than $1 \%$ for the medium and high projections.

Figure 12. Population 65 years and over at 2010 and for Projection Scenarios 2015-2030

Growth rates for the 65 years and over population are expected to be in excess of $2 \%$ per annum with the rate for the high projection being about $3 \%$ per annum. At 2030, this population group will account for an estimated $14 \%$ of the total population under all three growth scenarios. The ageing of the population which will emerge is also reflected in the changes in the median age of the population (table xxiv). There are small variations between the median ages for the three scenarios. The median age will increase from 29.7 years at 2010 by 8.1 years to 37.8 years for the low projection. For the medium and high projections the expected gains are 7.4 years and 6.9 years respectively to a median age of 37 years at 2030.

Table (xxiv). Median Age (in years) by Growth Scenarios, 2010-2030

| Year | Low Projection | Medium Projection | High Projection |
| :--- | :---: | :---: | :---: |
| 2010 | 29.7 | 29.7 | 29.7 |
| 2015 | 31.4 | 31.3 | 31.2 |
| 2020 | 33.3 | 33.1 | 32.9 |
| 2025 | 35.4 | 35.0 | 34.6 |
| 2030 | 37.8 | 37.1 | 36.6 |
| Years added 2010-2030 | 8.1 | 7.4 | 6.9 |

Age dependency ratios are presented in table (xxv). The table shows the ratios at 2010 and 2030 and the changes in percentage terms between the two periods. At the beginning of the projection period in 2010 there were about 38 persons of ages between 0 and 14 years and about 13 persons aged 65 years and over to every 100 persons of working age. The results of the projections show that by the end of the projection period child dependency will have declined considerably. The decline will be the greatest for the low projections, by $41 \%$ to 23 per 100 down from 38 per 100. For the medium projections the fall would be to approximately 26 per 100 . The high projections will show the smallest reduction, by $23 \%$ down to 29 per 100 . The position is reversed for the old age ratio. From the 13 per 100 at 2010, the old-age dependency ratio moves up to approximately 20 per 100 under all three scenarios, increasing by over $50 \%$ in all cases.

Table (xxv). Age Dependency Ratios by Growth Scenarios, 2010-2030

| Item | 2010 | 2030 | \% Change 2010-2030 |
| :--- | :---: | :---: | :---: |
| Low Projection |  |  |  |
| Child Dependency Ratio | 38.27 | 22.56 | -40.9 |
| Old-Age Dependency Ratio | 12.87 | 20.31 | 53.8 |
| Total Dependency Ratio | 51.14 | 42.88 | -17.1 |
| Medium Projection |  |  |  |
| Child Dependency Ratio | 38.27 | 26.23 | -31.5 |
| Old-Age Dependency Ratio | 12.87 | 20.12 | 56.3 |
| Total Dependency Ratio | 51.14 | 46.35 | -9.4 |
| High Projection |  |  |  |
| Child Dependency Ratio | 38.27 | 29.45 | -23.1 |
| Old-Age Dependency Ratio | 12.87 | 20.43 | 58.7 |
| Total Dependency Ratio | 51.14 | 49.88 | -2.5 |

## APPENDICES FOR POPULATION PROJECTIONS

## A. TECHNICAL NOTES FOR THE PROJECTION INPUTS

## B. MAIN TABLES

## APPENDIX A

## TECHNICAL NOTES FOR THE PROJECTION INPUTS

The purpose of this section is:
a. To explain main calculations used in the analysis
b. To describe the procedures for the calculation of the items of data required as inputs
c. To outline the specific steps in the process of inputting data and producing projections

## 1. Explanation of Calculation of Average Annual Growth Rate

Formula for Calculating the Annual \% Exponential Growth Rate:

$$
\mathrm{r}=\left(\mathrm{LN}\left(\mathrm{P}_{\mathrm{n}} / \mathrm{P}_{0} / \mathrm{n}\right) * 100\right.
$$

Where $r=$ rate of growth
$\mathrm{P}_{\mathrm{n}}=$ Population or value at initial date
$\mathrm{P}_{\mathrm{n}}=$ Population or value at later date
$\mathrm{n}=$ interval between the two dates

The census intervals ( n ) used for intercensal rates are shown below;

| Census Period | Interval (in years) |
| :---: | :---: |
| $1980-1991$ | 11 |
| $1991-2001$ | 10 |
| $2001-2010$ | 9 |
| $1980-2010$ | 30 |
| Projection Period |  |
| $2010-2015$ | 5 |
| $2015-2020$ | 5 |
| $2020-2025$ | 5 |
| $2025-2030$ | 5 |
| $2010-2030$ | 20 |

Note: (a) Projection periods are from mid-year to mid-year.
(b) All growth rates for the periods shown have been calculated using the intervals shown.

These calculations were done using Excel spreadsheets on CD ROM based on Donald T Rowlands, Demographic Methods and Concepts (see references).

## 2. To calculate fertility Inputs: age specific fertility rates and total fertility rate

a. Base data: Births by age of mother, 2000 and 2010

| Age Specific |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Age of Mother | Births 2001 <br> (1) | Female Population 2001 (2) | Fertility Rate (3) col 1/col 2 | $\begin{aligned} & \text { Births } \\ & \text { 2010(1) } \end{aligned}$ <br> (4) | Female Population 2010 (5) | Age Specific Fertility Rate <br> (6) col 4/col 5 |
| 15-19 | 695 | 8,345 | 0.08325 | 390 | 7,657 | 0.05122 |
| 20-24 | 844 | 6,715 | 0.12565 | 671 | 6,776 | 0.09959 |
| 25-29 | 799 | 6,604 | 0.12104 | 515 | 6,644 | 0.07796 |
| 30-34 | 644 | 6,185 | 0.10415 | 408 | 6,007 | 0.06831 |
| 35-39 | 355 | 5,915 | 0.05997 | 251 | 6,241 | 0.04045 |
| 40-44 | 97 | 4,663 | 0.02087 | 84 | 6,101 | 0.01385 |
| 45-49 |  |  |  | 4 | 5,393 | 0.00075 |
| Total |  | 38,427 | 0.51493 | 2,324 | 44,819 | 0.35213 |
| Total Fertility Rate |  |  | 2.57 |  |  | 1.76 |

Note: Slight adjustment made to rates for 2010.
b. Project the TFR based on assumption of a logistic curve using the PASEX worksheet TFRGLST (as discussed in Methods and Assumptions).

- This spreadsheet interpolates and extrapolates total fertility rates (TFR). The program fits a logistic function using 2 to 17 total fertility rates, given the values of upper and lower asymptotes. The beginning date for displaying the results is also entered.
- The asymptotes are values that the curve tends towards (but never actually reaches) i.e. their effect is to constrain the range of values of TFR that the curve can take within a certain range.
- The guidelines for using TFRGLST from the US Census Bureau are as follows:

If the lowest (normally the most recent) estimated TFR is greater than or equal to 2.0 and less than 3 births per woman, set the asymptotes as: lower $=1.7$ and upper $=4.0$.

If the lowest (normally the most recent) estimated TFR is less than 2 births but more than 1.7 births per woman, assume a linear change to 1.7 by the year 2050 .

The second option would apply to Saint Lucia with an estimated TFR of 1.76 at 2010. Rather than holding the 1.76 constant, the assumption for the current projections is that the TFR will decline to a level not lower than 1.55 by 2025 after which there is a small upturn to 1.61 by 2030 .

The process of estimating the future path of the TFR was carried out in two stages using the TFRGLST worksheet as follows:

- Stage 1. Set the lower asymptote at 1.55 and the upper asymptote at 7.00. For initial TFR, Date: 2001.50 (mid-year 2001), $\mathrm{TFR}=2.57$. Date: 2010.50 (mid-year 2010), $\mathrm{TFR}=1.76$.
Note: The format for the dates: year and fraction of year represents month and day (July $1=183^{\text {rd }}$ day of year $183 / 365=.50$ ).

## Output from TFRGLST Stage 1

| Year | $T F R$ | Year | $T F R$ |
| :---: | :---: | :---: | :---: |
| 2000.5 | 2.74091 | 2013.5 | 1.669281 |
| 2001.5 | 2.57 | 2014.5 | 1.648602 |

## c. To calculate age-specific fertility rates for 2010 and 2030

To obtain the age specific fertility rates for the end of the period use the ASFRATT worksheet from the PASEX series. The worksheet requires that the reported age specific rates for the base year and the desired TFR for the end period are entered. Age specific rates are then produced for the desired TFR.

## Output from ASFRATT and input for projections

TFR and age specific rates for base and end of period by projection type

## 3. To calculate Mortality Inputs: Age specific death rates and base year life expectancy

a. Calculate age specific death rates for 2010

The average of deaths from full year 2001-2010 was derived. This was used as input with the 2010 census population for the PASEX spreadsheet LTPOPDTH to derive smoothed age specific mortality (nqx) values and life expectancy at birth.

| Age <br> Group | Average Deaths |  | Census Population |  | Derived Age specific death rates |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Male | Female | Male | Female | Male | Female |
| 0 | 22 | 23 | 1,234 | 1,220 | 0.01783 | 0.01818 |

| $55-59$ | 36 | 19 | 3,143 | 3,268 | 0.05208 | 0.03744 |
| $60-64$ | 49 | 41 | 2,655 | 2,755 | 0.08257 | 0.05628 |
| $65-69$ | 48 | 37 | 2,057 | 2,263 | 0.12449 | 0.09612 |
| $70-74$ | 71 | 58 | 1,708 | 1,840 | 0.18355 | 0.13270 |
| $75-79$ | 75 | 59 | 1,135 | 1,408 | 0.28188 | 0.18836 |
| $80+$ | 162 | 197 | 1,467 | 2,230 |  |  |
| Total | 642 | 520 | 82,224 | 83,367 |  |  |

Note: (i) LTPOPDTH produces two abridged life tables at items C and D . D has smoothed nqx values which are the ones selected for use as inputs for the projections.
(ii) Mortpak calculates life expectancy which is not consistent with the assumed value for 2010. This does not present a problem as the mortality pattern is maintained.

## 5. To determine migration pattern by age

a. Use percentage distribution of migrants by age as shown in table (xiii) and apply to total net migration at the base year

|  | \% Distribution |  | Net Migrants |  |
| :--- | :---: | :---: | :---: | :---: |
| Age Group | Male | Female | Male | Female |
| $0-4$ | 4.3 | 3.7 | -15 | -16 |
| $5-9$ | 5.2 | 4.6 | -19 | -20 |
| $10-14$ | 6.0 | 5.5 | -22 | -24 |
| $15-19$ | 6.8 | 6.3 | -24 | -28 |
| $20-24$ | 7.0 | 7.2 | -25 | -32 |
| $25-29$ | 8.2 | 8.7 | -30 | -38 |
| $30-34$ | 9.2 | 9.7 | -33 | -43 |
| $35-39$ | 9.3 | 9.9 | -33 | -44 |
| $40-44$ | 8.9 | 9.2 | -32 | -40 |
| $45-49$ | 8.0 | 8.4 | -29 | -37 |
| $50-54$ | 6.8 | 7.0 | -24 | -31 |
| $55-59$ | 5.8 | 5.9 | -21 | -26 |
| $60-64$ | 4.9 | 4.5 | -18 | -20 |
| $65-69$ | 3.7 | 3.5 | -13 | -15 |
| $70-74$ | 2.8 | 2.6 | -10 | -11 |
| $75-79$ | 1.4 | 1.3 | -5 | -6 |
| $80+$ | 1.7 | 2.0 | -6 | -9 |
| Total | 100.0 | 100.0 | -360 | -440 |

## The PASEX Spreadsheets

The Population Analysis Spreadsheets are a set of Microsoft Excel workbooks developed by the United States Census Bureau containing frequently used procedures and methods in basic demographic analysis. The purpose of the workbooks is to facilitate analysis of available data on a range of topics including age structure. The spreadsheets and manuals are available for free download from the Census Bureau website:
https://www.census.gov/data/software/pas.html

## Data Sources

The data required for developing population projections using the cohort component method are taken from population censuses and vital statistics from the registration system of Saint Lucia while The United Nations Trends in International Migrant Stock, the 2017 Revision database provided migration data.

## Data Items for the projections

1. Mid-year population 2010 by age and sex.
2. Births by age of mother 2001 and 2010.
3. Deaths by sex and age 2001-2010.

## Summary of Data Inputs

1. Base Population by Age and Sex (the same for all projections)
2. Base Mortality Rates by Age and Sex (the same for all projections)
3. Fertility Rates by Age for Base date and for end date (Base date figures the same for all projections. End date figures will vary based on assumptions)
4. Migration Pattern: Number of Migrants by age and sex (the same for all projections).
5. Summary of Assumption Targets for Fertility, Mortality, Migration (will vary by projection).

## Inputting the data

The preparation of the population projections requires installation of the MORTPAK software. This can be downloaded free of cost from the following website. A manual explaining all the applications is also included. http://www.un.org/en/development/desa/population/publications/mortality/mortpak.shtml

On opening MORTPAK select the program projct.mpl The information and data items required are shown below

## GLOSSARY OF TERMS

Age Dependency Ratio - A ratio in which the numerator represents the total number of people not of working age (too old or too young to work and therefore "dependent" on those who do), and the denominator represents the population of working age; often multiplied by 100, which yields the number of dependents per 100 persons of working age.

Age-Specific Rate - A rate that relates a given demographic event at a specific age (or age group) to the corresponding at-risk population in the same age (or age group). For example, the age-specific fertility rate relates births to women in a specific age group to the total women in the same age group, and the age specific death rate relates deaths to the people in an age group to the population in the same age group.

Ageing is the process of growing older. For the population it is represented by a growing percentage of older persons.

Average Family Size is the average number of living children of an individual or couple.
Base Population - For population projections this is the starting population.
Child-Woman ratio - A measure formed by dividing the number of children (0-4) by the number of women of child-bearing age (aged 15 to 49 or 15 to 44 ).

Cohort - A group of people who experience the same demographic event during a particular period of time such as their year of marriage, birth or death.

Crude Rate - A rate that relates a demographic event to the total population and makes no distinction concerning different exposure levels to the event. Examples include the crude birth rate and the crude death rate.

Crude Birth Rate - The number of live births per 1,000 population in a given year.
Crude Death Rate - The number of deaths per 1,000 population in a given year.
Emigrant - A resident of a given country who departs to take up residence in another country.
Growth Rate - Often used as a general expression to describe the rate of change in a given population, even one that is declining.

International Migration - The movement across an international boundary for the purpose of establishing a new permanent residence.

Intercensal - The period between two successive censuses.
Interpolation - The calculation of intermediate values in a given series of numbers as for example estimating numbers of persons/events in single years of age from published data for 5-year age groups.

Life Expectancy - The average number of years of life remaining to a group of persons who reached a given age as calculated from a life table.

Life Table - A tabular display of life expectancy and the probability of dying at each age for a given population according to age-specific death rates prevailing at that time. The life table gives an organized complete portrait of a population's mortality.

Median Age - The age at which exactly half the population is older and half is younger. The age at which the population is divided into two equally sized groups.

Mid-year Population - Mid-year, taken to be July 1 is assumed to be the point by which half the changes in a population have occurred. The mid year population may be calculated as the mean, or average of the population at the start and end of the year.

Natural Increase - The excess of births over deaths in a population. The excess of deaths over births is referred to as natural decrease.

Net Migration - The difference between the number of immigrants and the number of out migrants for a given area over a given period of time.

Net Migration Rate - The ratio of net migration for a given area over a given period to the population.
Old Population - A population with a relatively high proportion of middle-age and elderly persons, a high median age, and thus a lower growth potential.

Population Change refers to change in the number of inhabitants of an area. The change may be an increase, a decrease or zero.

Postcensal - The period since the last census.
Rate of Change - The change of population during a given period expressed as a rate. The rate may relate to the entire period in which case the denominator is usually the initial population. Alternatively it may be an average annual rate in which case the rate may assume annual compounding, continuous compounding or some other function.

Rate of Natural Increase - The difference between the crude birth rate and the crude death rate.

Replacement Level Fertility is the level of fertility at which a cohort of women, on the average, has only enough daughters to "replace" themselves in the population. Once replacement level fertility has been reached, births gradually will reach equilibrium with deaths and in absence of migration a population ultimately will stop growing and become stationary. Replacement level fertility is attained when the TFR is 2.1 . An average of 2 children would 'replace' all mothers and fathers, but only if all the children survived to reproductive age. Thus an extra 0.1 is needed to offset the effects of premature mortality as well as the imbalanced sex ratio at birth.

Sex Ratio - The ratio of males to the number of females in a population usually computed for age groups and expressed per 100 females.

Sex Ratio at Birth - The ratio of males to female births.

Smoothing - The adjustment of data to eliminate or reduce irregularities and other anomalies assumed to result from measurement and other errors.

Survival Ratio - A rate expressing the probability of survival of a population group, usually an age group, from one date to another and one age to another. Life table survival ratios are calculated from the $\mathrm{L}_{\mathrm{x}}$ column. The forward ratio is $L_{x+t}$ where $t$ is a date in the future divided by $L_{x}$. For example, the survival ratio for age 15 in 10 years time is $\mathrm{L}_{15+10} / \mathrm{L}_{15}=\mathrm{L}_{25} / \mathrm{L}_{15}$. The backward survival ratio is $\mathrm{L}_{\mathrm{x}-\mathrm{t}}$ where t is a date in the past divided by $\mathrm{L}_{\mathrm{x}}$. For example, the survival ratio for age 2510 years before is $\mathrm{L}_{25-10} / \mathrm{L}_{25}$.

Total fertility Rate (TFR) is the average number of children that would be born alive to a woman (or group of women) during her (their) lifetime if she (they) were to pass through all the childbearing years conforming to the age specific fertility rates of a given year.
